# DILLON'S UNIVERSITY BOOKSHOP

1 MALET STREET, LONDON WC1A 7JB Tel.01-636 1577 (16 lines)

One of the world's leading booksellers, Dillon's invites you to choose from over 150,000 technical, academic and general titles covering all subject areas.

This large and varied stock enables us to provide a comprehensive service to both personal and Mail Order customers. We will post books to individuals and institutions in the United Kingdom and overseas, or arrange subscriptions to newspapers and journals. We also offer credit facilities, and a quotation service for large and small orders alike.

For further information, write to the Mail Order Manager with details of your requirements and subjects of interest.

## A hot new tracer for Vitamin D<sub>3</sub> studies

24,25-Dihydroxy[23,24(n)- <sup>3</sup> H]cholecalciferol	TRK.616	50-80 Ci/mmol (Current batch 80 Ci/mmol)
--	---------	--

### An important addition to the best range of Vitamin D<sub>3</sub> tracers available:

1α,25-Dihydroxy[23,24(n)- <sup>3</sup> H]cholecalciferol	TRK.588	70-110 Ci/mmol
25-Hydroxy[23,24(n)- <sup>3</sup> H]cholecalciferol	TRK.558	70-110 Ci/mmol
25-Hydroxy[26(27)-methyl- <sup>3</sup> H]cholecalciferol	TRK.396	5-15 Ci/mmol
[1α,2α(n)- <sup>3</sup> H]Vitamin D <sub>3</sub>	TRK.346	5-15 Ci/mmol

### Also available

[4- <sup>14</sup> C]Vitamin D <sub>3</sub>	CFA.455	25-35 mCi/mmol

# The Hypercycle

## A Principle of Natural Self-Organization

The Darwinian evolution of the species was, in all likelihood, preceded by an analogous stepwise process of molecular evolution. This hypothesis, developed by Nobel prize winner, Prof. Manfred Eigen and the renowned theoretical chemist, Prof. Peter Schuster, is presented here for the first time in book form. The authors suggest that hypercyclic organization led to a unique cell machinery operating by means of universal code. Originating in a molecular quasi-species, the hypercycle evolves by mutation and gene duplication into more complex forms.

Written with chemists, biochemists, biologists and physicists in mind, this book provides a deeper understanding of the origin and evolution of life, and will furnish the basis for many new experiments.

**Guide to authors**

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

**Manuscripts** may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (*a*) is preferred to  $e^a$  if '*a*' is more than one character.

**References** are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

**Artwork** should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely.

Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

*Nature's* publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976).

## Costs and benefits of carbon dioxide

THE release of carbon dioxide to the atmosphere by the burning of fossil fuels is, conceivably, the most important environmental issue in the world today. Whatever direction global energy policies take in the future, it is indisputable that carbon dioxide concentrations in the atmosphere will continue to rise. There is still uncertainty about the ultimate destination of carbon dioxide. It seems that roughly half the fossil fuel output has remained in the atmosphere, and early workers supposed that the remainder was consumed by the oceans and the biosphere. But the role of the biosphere is now a matter of hot debate. Some research has suggested that far from being a sink for carbon dioxide, the biosphere (through deforestation and changing land use) could actually be a source. Other work suggests the contrary, or that the role of the biosphere has actually changed with time. But it is inescapable that atmospheric concentrations have already climbed by 15% as a result of man's activities during this century and there seems little doubt that concentrations would be double present values around the middle of the next century if current growth rates for the use of fossil fuels (over 4% per annum) were to persist. This is unlikely, of course, given the depletion of energy resources, but at least the figure gives some sort of guide for realistic modelling.

Whatever the uncertainties about future emissions and the biosphere, there is no disagreement amongst researchers on the qualitative impact that an increase in carbon dioxide will have on climate: mean annual surface temperature will rise, and the rises will be greater at high latitudes. There is also consensus that the hydrological cycle would become more active—with precipitation and evaporation levels both rising. Beyond this there is still scope for quantitative disagreement, but a commonly quoted figure is that a doubling of atmospheric carbon dioxide would result in a world global annual mean surface temperature rise of 2 to 3 °C, with marked latitudinal asymmetry. As yet, however, no model adequately accounts for changes in the ice-covered regions of the world or in the hydrosphere (particularly ocean currents), and there is considerable room for disagreement regarding the importance of feedback effects arising from changes in cloud cover.

With so much uncertainty around, is it irresponsible

and premature to widen the debate at this stage from meteorologists and climatologists to those with interests in the consequences of climatic change—agriculturalists, glaciologists, oceanographers, economists, sociologists, political scientists and so on? Surely not, provided that sensible perspectives are maintained. A recent workshop jointly sponsored by the American Association for the Advancement of Science and the US Department of Energy has been attempting to lay transdisciplinary foundations for a federally supported research programme on the impact of increasing atmospheric carbon dioxide content and it is not too early for other nations (or more reasonably groups of nations, such as the European Economic Community) to take similar initiatives. Even if large amounts of money were not immediately forthcoming, there are still some links across the specialist boundaries which ought to be made now.

In the long run the United Nations presumably has to get in on the act, and the United Nations Environmental Programme will shortly be setting up a carbon dioxide committee. At first sight scientists might despair at the thought of yet another area in which there will be politicised conflict between industrialised nations, large-scale releasers of carbon dioxide, and the developing world, involuntary recipients of the consequences. But careful reading of what climatologists and meteorologists have to say by way of prediction makes it clear that there could be as many benefits as losses as a result of temperature and rainfall changes—and that some parts of the world may even become cooler.

There is no clear indication that the animal and plant kingdoms will as a whole prosper more or less in a changed climate. And there may be direct carbon dioxide effects, such as changes in the rates of photosynthesis and respiration, increases in the efficiency of plant water use and changes in nitrogen fixation rates. To be sure, the most widely publicised effect of a substantial global warming is the danger of the West Antarctic Ice Sheet breaking loose and melting, with highly predictable effects on sea level. But for the rest the picture is complex and by no means universally gloomy. The sooner some of the complexities are unravelled, the sooner the carbon dioxide problem can be intelligently injected into discussions of world energy strategies. □

# President Carter aims to spend 'windfall' oil profits on energy research

PRESIDENT Carter last week asked members of the National Academy of Sciences to support his proposal that Congress create an Energy Security Fund, financed by a tax on the 'windfall' profits which the oil companies are expected to make following the de-control of oil prices. Such a fund could partly be used to double US investment in energy technology over the next few years.

The President's remarks were made during the course of an address to the annual meeting of the academy, the first to have been delivered to the assembled scientists since President John Kennedy spoke at a NAS meeting one month before his assassination. The Energy Security Fund, he said, which Administration officials estimate could involve collection from the oil companies of up to \$7 billion a year, would be used not only to provide relief to those least able to pay for more costly energy, but also to finance projects, including both basic and applied research, important to the country's energy future.

"By the second quarter of the 21st century, we will have learned to rely on cleaner, essentially inexhaustible sources of energy. The principal candidates include, of course, fusion and solar technologies as photovoltaics," President Carter said.

"We are preparing right now for these stages of our energy future. Our energy research and development is already larger in its programme size than those of all our allies combined. But we must do more."

The President had particularly harsh words for the oil industry, which is suggesting that the extra money it receives from increased oil prices should be used to finance its own energy development programmes, covering both exploration and research. He accused the companies of trying to 'hoodwink' the American people by passing a windfall profits tax that was in fact designed to provide the companies with loopholes through which they could increase their general revenues.

"They will try to pass this charade off on the American people as a so-called 'plough-back' provision. But it is not a 'plough back'—it is a 'plough under' and 'kick back'. And what is going to be ploughed under is the Energy Security Fund with its aid to research and to the poor," the President said.

"I ask for your support in the battle to pass an honest windfall profits tax . . . and I also call on all of you

in the scientific and engineering community to fulfil the trust of the American people by creating the new energy technologies that are so vital to the future of our country."

Although many observers in Washington feel that the President's idea of a windfall profits tax has a greater chance of succeeding in Congress than when it was first suggested last month, some have expressed doubts whether the amount of money that the Federal Government could collect in this way would in fact be as high as the President has suggested.

A report by Ralph Nader's Tax Reform Research Group has said that the proposed tax would pick up "only \$3.4 billion of the new revenues, ie, 20% rather than 50% of the increased revenues that the oil companies are expected to receive.

However the chances of Congress accepting the idea have been increased by the large profit increases which the major oil companies have been reporting for the first quarter of 1979. Texaco Inc., for example, reported an 81% increase in profits over the same period last year, and Gulf Oil Corporation a 61% increase. A spokesman for the President said that these profit increases greatly strengthened the arguments for a windfall profits tax to be used for research and other purposes.

In his speech to the academy, President Carter also asked the scientists to support his attempts to have the new Strategic Arms Limitation Treaty (SALT II), currently in the closing stages of negotiation with the Soviet Union, ratified by the US Senate.

Of all the fruits of science none is more bitter than nuclear weapons. And of all the responsibilities of nations, none is more urgent than the control of this most terrible menace to our

lives and to our civilisation," he said.

Many of the issues involved in assessing the treaty were very complex technically, and the American people would look to the scientific community to help shape an educated public debate. "Many of you devoted much effort to the debate over SALT I, and you played a major role in forming the consensus that developed to support that treaty. Today I ask for a renewal of that commitment."

The President also referred to the increasing costs of major scientific experiments—in contrast to the situation facing scientists such as Albert Einstein who required "little more than a few sharpened pencils and a quiet place to think"—and the choice that this posed between doing experiments on one's own, or in co-operation with other countries.

"We must continue to choose cooperation—for reasons that go beyond the considerable benefits of sharing costs and sharing ideas," the President said. "With our traditional friends, scientific and technological cooperation can strengthen existing bonds. With others, who may not be so friendly, it can help to bridge political, ideological and cultural division."

David Dickson

## More US accidents in transporting chemicals

THERE has been a sharp rise in the numbers of accidents and deaths involving the transportation of hazardous materials such as liquefied natural gas, sodium sulphhydrate, anhydrous ammonia and chlorine, according to a report published last week in Washington by the research service of the Library of Congress. According to the report, there were 45 deaths and 1,411 injuries involving the transport of hazardous materials in 1978, compared to 32 deaths and 749 injuries in 1977 and an average of 21 deaths and 592 deaths over the previous

period. The high accident rates in 1978 had partly reflected two major incidents, the explosion of a tank-car in Waverly, Tennessee, which killed 15 persons and injured 48 others, and the derailment of a goods wagon in Youngstown, Florida, which resulted in eight deaths and injured 158. The report says that present federal inspections may not be adequate, citing the fact that the Department of Transportation's Material Transportation Bureau has only six full-time inspectors to cover 20,000 container supply firms and 100,000 shippers. □

## Critics challenge data that led to 2,4,5-T ban

THE recent decision by the US Environmental Protection Agency to issue an emergency order banning the use of the herbicide 2,4,5-T has attracted strong criticism from its manufacturers. They are contesting the EPA's decision in a Michigan district court, claiming that it is based on a "seriously flawed study" and a misreading of data by the EPA to draw conclusions to support the ban.

The ban on 2,4,5-T (2,4,5-trichlorophenoxyacetic acid) was made when a study in the Alsea region of Oregon found a strong correlation between the use of the herbicide and a tripling in the rate of spontaneous abortions among local women. The study was conducted by Dr Eldon Savage of the Epidemiological Studies Programme of Colorado State University and commissioned by the EPA. It was the second investigation into the health effects of 2,4,5-T on residents.

The first study—"Alsea I"—was inconclusive, according to the EPA, and led to the conclusion that the claims of Alsea women that their miscarriages were due to 2,4,5-T "had not been demonstrated from the data presented." However, the spontaneous abortions did appear to follow a seasonal pattern and 10 out of the 13 cases under investigation occurred between April and September; whereas hospital records indicated that increases in spontaneous abortions normally occurred in January-March and October-December.

Alsea II was designed to eliminate any element of bias which may have occurred in the first study, and covered a much larger sample. A 1,600 square mile rural area where 2,4,5-T spraying had taken place was chosen, with another 1,000 mile rural area and an urban area as controls. Data on spontaneous abortions in the first 20 weeks of pregnancy was taken from the records of hospitals in these areas.

The study revealed that the spontaneous abortion index (ratio of abortions/live births) was higher in the study area than in the other rural area. For the months of May, June, July and August, the index for the study areas was 89.9, 130.4, 105.4 and 88.1 compared with 63.2, 46.0, 55.3 and 79.8 for the rural control. In the urban area ratios were even lower. The investigation also showed a significant correlation with the 2,4,5-T spray pattern with a lag period of two to three months. The residents, the study suggests, could have come into contact with the herbicide and its dioxin (2,3,7,8-tetrachlorodibenzo-p-dioxin) contaminant in drinking water or through eating fish or other wildlife.

One critic of the Alsea II findings is Professor Nathan Mantel, a statistician at the biostatistics centre of George Washington University, Bethesda. He claims there are "fundamental statistical and logical flaws" in the report. Mantel was asked to review the report by the National Forest Products Association (2,4,5-T is in widespread use in forestry) and his comments have been forwarded to the EPA. He says the EPA were wrong to compare results for a rural study area and an urban control. His analysis revealed no statistically significant differences between the data taken from the study area and a third "control" area.

Referring to the Alsea findings of a correlation between spray times and the seasonal pattern of abortions, Mantel insists that the comparison was based on an improper statistical approach. He claimed this result was of little value anyway, since there was no statistically significant difference in the overall rates of abortion in the areas investigated—the EPA study reported little difference in the percentage of hospitalised spontaneous abortions for women aged 20-49 in the three areas.

Concern about the EPA's misreading of data centres on its use of material from Seveso in Italy. Residents of this town were exposed to dioxin in July 1976 following an accident in a reactor manufacturing trichloropheno. With dioxin known from animal studies to be teratogenic there was concern that the chemical would cause malformation to increase in the Seveso children.

The EPA says this is precisely what happened, and that there was sevenfold increase between 1976 and the first five months of 1977. While admitting that the data collected at Seveso was inadequate, and that there were "methodologic deficiencies" in the way it was analysed, the EPA nevertheless says that the evidence provides "suggestive indications of a possible teratogenic effect [by dioxin] in humans".

Many scientists insist that the EPA is wrong on this point. The EPA has been sent evidence to show that the increase in malformations at Seveso is due to better reportage of these cases and that the increase is more apparent than real. The Italian Parliamentary Commission report on Seveso reached similar conclusions and pointed out that, while many scientists believed that dioxin was potentially teratogenic in humans, the evidence to confirm this point has so far not been found. Furthermore, if dioxin had been responsible for an increase in malformations at Seveso, then there should be evidence of an increase in specific defects. However, the data does not show this pattern.

The Michigan court hearing on 2,4,5-T will have to consider these conflicting claims. A decision to uphold the EPA ban will not have serious economic repercussions on the manufacturers of 2,4,5-T through loss of sales; it will leave them open to compensation claims from women who have miscarried.

## Windscale leak: Benn calls for public inquiry into safety

Mr Tony Benn, UK Energy Secretary, has called for a full public inquiry by the next government into the Windscale leak which was found last month during borehole sampling near a temporary storage tank for highly active liquid waste, dissolved in nitric acid prior to concentration and final storage. At a local Labour Party meeting on Saturday, Benn expressed concern about the present leak as well as about "the continuing and unsolved leak of less active substances that has been going on for several years." Benn asked the Nuclear Installations

Inspectorate whether Windscale should be closed but was advised that this step was unnecessary.

Friends of the Earth has asked Peter Shore, UK Environment Secretary, to conduct an inquiry into other Windscale incidents which include possible leaks from the low level waste burial ground, the discovery of  $^{137}\text{Cs}$  and  $^{60}\text{Co}$  on surface water drains, the closure of building B204 because of radiation hazard and the discovery last year of plutonium on a half incinerated dismantled cooling tower.

The outstanding problem of the

present leak is to determine the probable rate of migration of activity from the region of the borehole. Material which has continuously leaked from the sump has progressed to a distance of 10 metres in a year. With the leak stopped, future migration depends critically on the detailed site geology. Preliminary BNFL measurements indicate that an average migration rate is about a metre a year, but according to Friends of the Earth there has never been a full geological site survey at Windscale.

# DESY makes a bid for protons in Hamburg

DESY, the West German subnuclear physics laboratory, appears to be establishing a rapprochement with CERN, Europe's international centre for the subject. It could rest on DESY building a superconducting storage ring for protons of around 280 GeV, while CERN builds LEP, a device for colliding 80 or 90 GeV electrons with positrons.

DESY would collide the protons with the electrons of its latest electron storage ring, PETRA, thus providing itself with the world's most precise instrument for probing the structure of the proton. LEP would be the most advanced tool for creating new forms of matter, such as new quarks, the intermediate vector boson, and Higgs particles.

This plan, which has yet to be formally adopted by the European high energy physics community, emerged at last week's inauguration ceremony for PETRA, held at the DESY laboratory in Hamburg. Professor Schopper, the director of DESY, told *Nature* that towards the end of this year he would be making an application to the German government to build a proton storage ring within the PETRA tunnel. The cost would be "about 1½ PETRAs"—around 150 million DM.

Earlier, the West German minister for science, Dr Volker Hauff, had made an extremely positive speech on behalf of basic science, from which it seemed clear that he would treat such an application sympathetically. "Political freedoms are inconceivable without a free science", he said unequivocally. However funds were limited (whereas research was unlimited) and choices had to be made. "We've got to limit ourselves to what we can do particularly well, where we can teach others and create top performance . . . with PETRA we do have a chance of creating this performance".

"With pride we can look forward to the development of PETRA as a centre of international research", said the minister. "More than half the researchers are guests, contributing their intellect and funds. PETRA is fundamentally enriched in this way."

And on the relationship of DESY and CERN, he said: "Very soon we will begin a dialogue with scientists to see if Germany can contribute to LEP. To have two flourishing laboratories, like CERN and DESY, is commensurate with the size of this continent. We cannot discuss the future of the one laboratory without thinking of that of the other."

This mood was reflected by Professor Jean Teillac, the President of CERN

Council, the supreme body directing CERN, who said that "with CERN and PETRA Europe has a good, well-balanced programme . . . More even than in the past we must use central facilities like CERN and DESY".

Meanwhile, the new cooperative mood has yet to be translated into firm proposals by ECFA, the European Committee for Future Accelerators, which is currently deliberating on the

question of the precise energy for LEP—a delicate matter because costs increase rapidly with energy, particularly at CERN, where a big LEP would have to burrow under the Jura mountains.

"But we are not letting politics get in the way of our judgements", the chairman of ECFA, Professor Marcel Vivargent, said last week.

RF accelerator cavities at PETRA: resonances are causing beam losses

## PETRA in a race to highest energy

PETRA, the world's largest electron-positron colliding beam device, is still having trouble reaching design luminosity at its highest energy—and is beginning to fear the strength of the American competition, PEP, under construction at Stanford, California.

PETRA, the brightest jewel of West German sub-nuclear physics, is hoped to make two major discoveries: the mass of the sixth quark, "top" (or "truth"), and the first indication of the masses of the intermediate vector bosons (IVBs), the particles whose exchange is believed to be responsible for the weak nuclear force. But both experiments need the highest PETRA energies, and a reasonable data-taking rate.

Last week PETRA was brought up to 26 GeV, and 10 events—the results of collisions between 13 GeV electrons and 13 GeV positrons—recorded in two detectors. But the "luminosity" (effectively, the data rate) was a factor 70 below design, producing something of the order of one event per hour. At this rate the experiment to detect the IVBs—an ambitious construction by Nobel laureate Sam Ting—would take 50 years. "Top" might be found by chance, but really requires a systematic energy scan, which would also take a long time at current rates.

The problem appears to be due to the fact that PETRA must accelerate its own electron and positron bunches from 6.5 GeV, thus moving through a number of electromagnetic resonances in the 32 accelerating cavities. (Until now, at lower energies, PETRA

has used only four cavities.) The resonances make handling the beam a rather tricky procedure, and the beam is frequently lost.

PEP, on the other hand, which is due to come on line at the end of this year, takes injection from the Stanford linear accelerator at 17 GeV for positrons, and 24 GeV for electrons, thus scaling PETRA's "ramping" problems at one leap.

However a glass of water may be half full or half empty, and one's view of PETRA's difficulties depends on which side of the fence one sits. On the one hand the experimenters, such as Ting's group, appear to be pessimistic; but the accelerator physicists, whose job it is to produce the beam, hand-wave hopefully. Only time will tell who is right.

Robert Walgate

PETRA's first event at 26 GeV shows jet structure

# A Ukrainian line on science and education?

SCIENTIFIC research and education in the Ukrainian SSR is failing to meet the demands of the "scientific and technical revolution", according to Volodymyr V. Shcherbyts'kyy, first Secretary of the Central Committee of the Communist Party of Ukraine.

Addressing a meeting of university and college lecturers, Shcherbyts'kyy called for a "comprehensive attitude" to research, in terms which could be taken as a criticism of current Soviet policy.

Of recent years, policy has stressed the development of close contacts between academic institutions and local industry, with the scientists undertaking R & D on a contract basis as and when required. This, in Shcherbyts'kyy's opinion, is simply inadequate.

"Contracts between higher educational institutions and production are still essentially reduced to the conclusion of economic agreements with the neighbouring enterprises, and these agreements are frequently aimed at accomplishing particular, minor, tasks", he said. "A solution at the level of the entire branch practically never occurs".

What precisely Shcherbyts'kyy had in mind is not entirely clear. Presumably he would replace the present *ad hoc* trouble-shooting with a more structured programme of problem-orientated R & D, somewhat on the Polish model. Such a system, he im-

plied, would need to be organised on the regional level by the Ukrainian republic.

At present, he said, the Ukrainian Ministry of Education "has no joint plans with any [other] Ukrainian Ministry", although it is carrying out "several comprehensive plans" with the All-Union Ministry of the Chemical Industry. This lack of contact with production at the republic level, said Shcherbyts'kyy, is apparently why only about 20% of the inventions patented by scientists at higher educational institutions in Ukraine ever get applied in industrial production.

The relationship between the economies of the Union Republics and the central planning authorities is a complex one, and the relevant paragraphs of the new Soviet constitutions do little to clarify the matter.

Long ago in the 1950s Khrushchev tried to over-ride the republic boundaries with a system of arbitrary economic planning regions. Although this set-up has been abandoned, at least as far as education and academic life is concerned, there has been a constant trend towards centralisation in the last two decades.

Recently, scientific publication in languages other than Russian has virtually ceased, and several promising lines of research in individual republics disappeared into main-stream anonymity. The distinctive Ukrainian

school of cybernetics of the early 1960s was probably the most notable such loss. Young graduates on leaving university are drafted wherever the economy requires—generally to the new towns of Siberia.

To date Shcherbyts'kyy has shown no signs of Ukrainian national sentiment—indeed, he was appointed in 1972 to replace Shelest, who fell from power precisely for his overly-Ukrainian attitude.

So First Secretary Shcherbyts'kyy's advocacy of strengthening academic-production contacts at a republic level seems essentially a pragmatic response to a pressing economic need, not a criticism of Soviet "nationalities policy", which to date he has resolutely supported.

On educational policy, however, he does seem prepared to make a cautious criticism. After noting "frequent cases of formalism", "unproductive use of time" and "a peculiar percentage mainia" in assessing the knowledge of students", he went on to the "participation of pupils and students in construction detachments and in agricultural operations"—officially viewed as a major factor in communist education.

Although paying official tribute to the "importance" of such activities, he nevertheless found it "necessary to emphasise that studies must be the first objective to which the student must apply his efforts". **Vera Rich**

## Soviet soil erosion laboratory defends its economic record

Moscow University's laboratory of soil erosion and river bed processes is already saving the Soviet economy some 10 million roubles per annum. So said its director, Dr Roman S. Chalov, interviewed on Moscow radio last month on the tenth anniversary of the opening of the laboratory.

Appraisal of R & D in terms of pay-off and cost-effectiveness is a regular Soviet practice—although perhaps more common among policy-makers than scientists.

Dr Chalov's laboratory, however, is in a somewhat sensitive position. Last December, the Party Central Committee and the USSR Council of Ministers adopted a resolution "On additional measures to strengthen nature conservation and to improve the use of natural resource, and among the sectors singled out for special criticism, the resolution mentions soil erosion, which the planners note "is doing considerable harm to the national economy".

Dr Chalov's laboratory, being the only one in the Soviet Union specifically devoted to erosion problems, can hardly have taken this observation lightly. Chalov's anniversary interview accordingly became an apologia for the work of the laboratory. The 10 million per annum, he implied, was merely an earnest of what the laboratory hopes to do.

At present the team are largely concerned with feasibility studies. In the North Caucasus agricultural area, a study has been made of the economic efficiency of different anti-erosion measures, giving special attention to the "accelerated erosion" produced by agriculture. A further field study will be undertaken this year in the non-black soil zone of the Russian SFSR. Development of this region of relatively poor agricultural land has a special place in the current Five Year Plan. Here the team will study gully erosion—the destruction of the land by flash floods and torrents.

This extensive programme of anti-erosion work, actual and potential, has one rather surprising omission. It is entirely water-related, and has no concern with wind-erosion and desertification. This is the more surprising since Khrushchev's policy of horizon-to-horizon cultivation of the virgin lands has created a number of incipient dust-bowls.

Desert erosion, is the concern not of Moscow University, but of Leningrad. A major expedition from Leningrad University and the Main Geophysical Laboratory last summer made a detailed study of the formation and growth of dust-storms in Soviet Central Asia.

According to the teamleader, Dr Kiril Kondrat'ev, the main subject of study was the "anti-hothouse" effect, which occurs during dust-storms which extend to high altitudes, cooling the Earth's surface by reflecting solar radiation.

# Third World to demand new fund for scientific development

THIRD World countries are making a strong bid to have the creation of a new fund for scientific and technological development occupy a prominent position on the agenda of the United Nations Conference on Science and Technology for Development (UNCSTD), which takes place in Vienna at the end of August.

The new fund is currently referred to as the International Science and Technology Development financing system. It is among the proposals submitted to the UNCSTD secretariat last week by the Group of 77—the organisation which represents over 100 developing countries—as a possible re-drafting of a proposed programme of action to be adopted by the conference.

At present there is still considerable disagreement among members of the Group of 77 over precisely what form the fund should take and how it should operate. However, some broad principles have been agreed, such as the fact that it should operate within the United Nations system, and that it should also provide relatively stable and continuous funding, to avoid problems for scientific programmes caused by intermittent or fluctuating support.

Other proposals that have been made are that the fund should be made up of contributions based on agreed percentage of the average deficit in the trade balance in manufactured goods between the developing and developed countries; that it be financed in part through a reduction in armaments expenditure by the developed countries; and also that further funding might come from a tax paid by developed countries to compensate for the brain-drain from developing countries.

The developed countries, however, have already made it known that they will be very reluctant in Vienna to accept any proposals which will require to provide substantial increases of funds. The issue is therefore likely to be one of the most hotly discussed during the conference.

The two other main issues likely to generate debate, it emerged from last week's meeting of the conference's preparatory committee in New York, are the development of appropriate institutional mechanisms—including the rearrangement of responsibilities for science and technology within the UN system—to support any policy recommendations made by the conference, and possibly some specific proposals for ways of stimulating collaborative research on topics of particular interest to developing nations.

The developing nations are more concerned at present about financial mechanisms and about institutional arrangements—the developed nations about specific research proposals. As things stand at present it seems unlikely that any major changes will emerge directly from the conference itself (restructuring of the UN system, for example, can only be done by the General Assembly). But there are still hopes that the conference will produce guidelines representing a consensus on how each of these three items should be approached.

The main development in the conference preparations since the last meeting of the preparatory committee in New York in February has been the efforts of the Group of 77 to develop a unified position which the developing nations can present at Vienna.

A working party of the Group of 77 met in New York for the first two weeks in April to prepare a set of amendments to the preliminary draft programme of action which has now been drawn up by the secretariat under three headings: strengthening the scientific and technological capacities of developing countries; restructuring the existing patterns of international scientific and technological relations; and strengthening the role of the United Nations in science and technology and the provision of increased financial resources.

In parallel to this effort the economic commission for Latin America organised a meeting of a group of experts in Lima, Peru, in March to discuss possible financing mechanisms to provide additional support for science and technology in developing countries,

making various proposals which, although not officially endorsed by ECLA, have been partially amalgamated into the Group of 77.

At the end of last week, the Group of 77 presented to the preparatory committee its suggestion on revising the first part of the draft programme of action, that which deals with internal arrangements within countries for developing science and technology.

Many of the suggestions such as the need to establish science and technology policies as part of general development policies, and to encourage cooperation between developing and developed countries, as well as between developing countries themselves, had already been made by the secretariat itself on the basis of the suggestions contained in the various national and regional papers which have been prepared and submitted as part of the planning process for this conference.

With regard to financial resources, the group of 77 says that present funding mechanisms for enhancing national science and technology systems "are highly unsatisfactory both from the qualitative and quantitative considerations" and adds that experience has shown that "there is need for a more effective financing system within the United Nations system for strengthening the science and technology capacities of developing countries".

In general the developing countries suggest that developed countries should devote on an annual basis 0.05% of their gross national product to the solution of scientific and technological problems of developing countries, and devote at least 10% of their R & D expenditure to programmes designed to solve problems of specific interests to developing countries.

More specifically they recommend the setting up of an International Science and Technology Development Financing System to provide financial resources to supplement national science and technological financing capabilities.

Precise details of how this system would work were still under discussion by the Group of 77 at the beginning of this week. In an earlier draft of possible recommendations prepared by the working party, however, it was suggested that any new system of financing be based on a number of features, including provision that money be made available on a predictable and continuous basis, and that it should be based on a linked to international economic parameters which reflect the present asymmetries between countries in technical capacity.

Appropriate provision should be made, the working party suggested, for the financing system to involve the use of regional funds, for which the ad-

"Every time they make a bomb, we make a killing!"

ministrative responsibility would be bestowed on the developing countries themselves, while overall responsibility would rest with the UN general assembly.

Detailed discussion on these various points are likely to occupy much of the time up to the Vienna conference. Meanwhile, in an attempt to make sure that something of a more immediately practical nature emerges from UNCSTD, various countries are sup-

porting proposals that specific efforts should be made to establish projects in areas requiring greater research. Belgium, for example, submitted a resolution to the preparatory committee last week suggesting five areas for international collaborative research: solar energy, rural development technologies, tropical diseases, methods of increasing food production, and an inventory of natural resources.

David Dickson

## Agricultural research centres transformed

THE dozen international agricultural research centres set up between 1959 and 1976 to conduct research into problems of tropical agriculture have had considerable influence on the national research systems of many developing countries as well as on the crops and methods used by farmers. The very changes the international centres have stimulated, however, have in turn resulted in changes being made to the mode of operation of the centres themselves so that they are no longer working to the rules laid down when the first, the International Rice Research Institute, was set up twenty years ago.

Speaking to a small gathering at the Science Policy Research Unit, University of Sussex last week, Dr Edward Clay of the university's School of African and Asian Studies said that the international centres had greatly influenced the way scientists in third world countries "perceive the research they're to carry out". In particular ever since IRRI and the International Center for the Improvement of Maize and Wheat (CIMMYT), the first two centres to be set up, achieved considerable success in breeding high-yielding dwarf varieties, most research on increasing yields for all sorts of crops in many countries has centred on finding dwarf varieties.

In India, for example, rice research has tended to focus on light-yielding semi-dwarfs for irrigated land. 67% of rice breeding is oriented towards irrigated rice, even though only 28% of the land used for rice cultivation is irrigated. And almost all the new varieties developed have been semi-dwarfs. Only 5% are suited for deep water although 40% of the land used for rice growing is under deep water.

According to Dr Clay, the international centres cannot be held entirely responsible for this mismatch of research to needs although it is highly likely that they have had some influence. In the case of rice research, for example, IRRI has mainly concentrated on irrigated rice—simply because of the local conditions around its home in the Philippines.

The centres' influence, however,

claims Dr Clay, extends beyond the individual scientist to the very agricultural policy of developing countries. "Experts were put into the international centres and were successful", he says "therefore the model of a centre was seen as a good recipe for success". More international centres were built and individual countries began to build their own single purpose centres. The Bangladesh government, for example, decided to create one specific rice research institute—"very large, costly and capital intensive with well-trained scientists". This was a new idea for an individual country—even countries with a highly organised research effort such as the US and Japan had not concentrated their research on just one topic into one place.

When IRRI and CIMMYT were first set up, they were intended to be solely research centres where Western scientists could apply certain techniques which had proved beneficial in agricultural research for temperate zone crops to tropical crops. As the influence of these first two centres spread, however, and individual developing countries began to take up their methods, they have played an increasing role in educating third world scientists and organising exchanges. With the creation of the Consultative Group for International Agricultural Research (CGIAR) "to raise funds and establish research policies" for the centres and the creation of more centres in different parts of the world, their operation has gradually become more bureaucratic.

"We now have well-defined bureaucratized institutions", according to Dr Clay. "This was not true of the original centres. In expanding and replicating the original model we've now got something quite different". There is now pressure for the centres to work much more with developing countries than was initially intended. And, according to Dr Clay, as they are essentially funded by industrialised countries this has put them into a complicated relationship between the aid-donors and their recipients.

Judy Redfearn

## Pre-UNCSTD colloquium planned

PREPARATIONS for the Colloquium on "Science, Technology, and Society" to be held by the UN Committee on the Application of Science and Technology to Development (ACAST) in Vienna next August immediately before UNCSTD, were the main item on ACAST's agenda when it met in Geneva recently. At the Colloquium 200 invited representatives of the world scientific and technological community will help formulate a document for discussion at UNCSTD.

During the first week of the ACAST meeting it became apparent that the Colloquium is seen only in terms of certain items of the agenda of UNCSTD. For whatever reasons, the members of ACAST seem to have forgotten their hitherto jealously guarded role as an independent advisory committee, and limited themselves mainly to points they had been asked to consider by UNCSTD Secretary-General, José da Costa.

However, da Costa himself possibly helped to harden ACAST's attitude. His personal intervention on a flying visit, during which he did not even stop to answer many of the questions he inspired, appeared to reflect considerable pessimism as to the outcome of his own Conference. Seeing less than a fifty-fifty chance of any concrete results, he feared it would be only a "conference verbale", within which ideas on, amongst other things, new forms of cooperation between North and South, as well as within the South might at best appear in the form of recommendations.

Da Costa's statement was also noteworthy for a sudden and highly emotional attack on the way in which his conference is being treated by the media, in particular by the "Lund Letter", published by an internationally-oriented group in Sweden, and which he singled out as "nordique et paranoïaque".

A second factor which further enlivened the ACAST proceedings was what looked remarkably like an attempt on the part of UNESCO, through their representatives at the meeting, to take over the whole Colloquium, albeit still disguised as an ACAST-sponsored meeting. Whether this was because of their frustration at the admittedly somewhat tardy and, to some observers, impractical way in which the Colloquium was being planned and organised, is not clear.

However, here the members of ACAST closed their ranks and refused to be stampeded by UNESCO's probably justified calls for urgency.

Peter Collins

## news in brief

**UN urged to take lead in studying effects of CO<sub>2</sub>:** The United Nations Environment Programme can and should take the lead in assessing the global impact of an increase in carbon dioxide on the environment and health and society generally, Mrs Barbara Blum, deputy administrator of the US Environmental Protection Agency, told UNEP's governing council in Nairobi last week. She also called for an international meeting of experts to accelerate and coordinate action to improve management of the world's forests. "Tropical forests are the world's richest generic reservoir, a potential source of useful plants and drugs, a modulator of climate, a shield against desertification and soil loss, and a renewable timber-bank", she said. "It is time to highlight this key problem for decision-makers at the highest level of government."

Recent experience in the US, which was now having to clean up the consequences of earlier indiscriminate dumping of toxic wastes, showed that the land was not an infinite sink or sponge which could be used as a dumping ground for residues of industrial activity.

**Russian invitation:** France has been asked to supply a cosmonaut for a space flight with a Soviet crew. This proposal was made by Mr Brezhnev to President Giscard d'Estaing, during the French leader's visit to Moscow last week. According to Tass, Giscard "responded positively".

**TUC gets in on microprocessors:** Two weeks after the UK Science Research Council jumped into the technology of microprocessors with proposals for a major research and training programme (19 April), the Trades Union Congress has urged full cooperation between government, management and the unions to avoid the loss of "hundreds of thousands of jobs". Mr Len Murray, TUC general secretary, notes in a report that "in the absence of intervention and planning, the benefits of microelectronics will certainly be unequally distributed". The TUC calls for a 35-hour week, a reduction of systematic overtime, longer holidays and sabbaticals and trade union education in microprocessor technology. But Professor Kristen Nygaard of the Institute of Informatics of the University of Oslo says that the key issue is one of workplace control. He cites the introduction of "data" shop stewards in Norway as a more appropriate demand for trade unions to make. The shop stewards serve on small shop floor committees of four to six persons and they are not permitted to become programmers. The stewards are also required to attend the annual data processing course given by the Norwegian TUC that has been held since 1971. *Employment and Technology. TUC, Great Russell St., London WC1. 40p.*

**Cornell ring starts storing electrons:** The first circulating beam of electrons has been stored at Cornell University's new Electron Storage Ring, a facility which, when fully operational later this year, will enable stored beams of electrons and positrons to collide at two points in their orbit. The storage ring is mounted in the same tunnel that houses the Cornell electron synchrotron, which will provide the high energy electrons and positrons for injection into the storage ring. Conversion of the synchrotron into a colliding beam facility has been under way since September 1977, and has been funded at an estimated cost of \$20.7 million by the National Science Foundation.

**Head of FDA resigns:** Dr Donald Kennedy has resigned as director of the US Food and Drug Administration, an agency of the Department of Health, Education and

Welfare, to return to Stanford University in California where he is to become provost and vice-president for academic affairs. Before joining the FDA in March 1977, Dr Kennedy was professor and head of the human biology programme at Stanford. For a time he was also presidential science adviser, acting as one of two senior consultants to the Office of Science and Technology Policy. Announcing his decision to return to academic life, Dr Kennedy said he had intended to stay at FDA through a full academic term, "but the position at Stanford will not wait". He leaves the FDA on June 30—one day before a tough new ethics law restricting the contacts that ex-government employees can have with their previous agencies comes into effect—and starts work at Stanford on August 1.

In his two years at the FDA, Dr Kennedy has been at the centre of a number of controversial issues. He has strongly supported attempts to ban saccharin as a potential carcinogen, and has strongly opposed moves to legalise the medical use of the claimed anti-cancer agent laetrile. Last year he was also behind unsuccessful attempts by the administration to overhaul FDA's drug-regulation system.

**New analysis traces consequences of world resource depletion:** Worldwatch Institute, a Washington-based non-profit research organisation, has released a study on the economic effects of population growth, which finds that significant per capita declines are occurring in four major resource areas: fisheries, forests, croplands and grasslands. Over-fishing has become the rule rather than the exception. In forestry, demand has exceeded the sustainable yield of the world's forests producing higher costs for lumber and a consequent shortage of housing. Grassland management is characterised by overgrazing on every continent and pressure on beef, milk, wool and leather production. Crops are also strained, and cereal production, which increased 30% from 1950 to 1971, has levelled off.

The study points out that when biology starts to fail, oil tends to be substituted, thus placing a drain on energy reserves. Synthetic fibres now account for a third of the market and synthetic rubber two-thirds. Cardboard and wood are replaced by plastics. In addition, agriculture depletion increases the demand for chemical fertilisers and mechanised agriculture to maintain production. Worldwatch says: "The oil safety valve is starting to stick." The study is critical of supply and demand solutions and sees a need for government intervention in population policy and resource management and increased research into the capacity of the world's biological systems.—*Resource Trends and Population Policy: A Time for Reassessment. Worldwatch Paper 29.*

**Sino-Bangla technical cooperation:** China and Bangladesh have signed an agreement for the mutual exchange of scientists and technicians to study agricultural production. China will organise study visits for Bangladesh experts in the freshwater fish farming, paddy rice culture, small irrigation projects and agricultural machinery manufacture. Also included will be the processing of green tea and Chinese medicinal herbs and visits to study the use of natural gas for producing chemical fertiliser. Bangladesh will offer study visits on jute manufacture, black tea growing and cultivation of mango saplings. About 50 Bangladeshis will visit China in the first group which will leave in the next two months. Bangladesh has been aligned towards Western technological development but the Chinese agreement may open up opportunities for the transfer of traditional technologies based on local resources.

# Multi-mirror telescope confounds the sceptics

**David Dickson** reports on a telescope with a radical new design which is to be officially inaugurated in New Mexico next week

FROM the main road it looks like a huge, gift-wrapped Christmas present, perched precariously on the summit of the 8,500-ft Mount Hopkins, 25 miles south of Tucson, Arizona. Only as you cover the last, steep stretch of the approach road and begin to glimpse the apparatus behind the rolled-back doors, does the building's function as an observatory become apparent—despite the absence of the conventional split dome.

Even then, the surprises are not over. Rather than the long, carefully balanced cylindrical telescope that one expects, there is a squat, almost cube-shaped construction with six identical mirrors hidden in a complex of steel girders, the whole apparatus supported by a massive steel yoke.

The Multi-Mirror Telescope, has been built jointly by the Smithsonian Institution and the University of Arizona, and is to be officially inaugurated next week. Attending the dedication ceremony may well be some of those who were initially sceptical about the feasibility of combining six separate reflecting mirrors in a single telescope, a step which the designers claim to be the first major departure from conventional optical telescope construction in more than a century.

"It is a radical design, and it met with an enormous amount of scepticism in the beginning. Even those involved in the project found they had to overcome some of their own biases and prejudices", says Professor William F. Hoffmann, of the University of Arizona's department of astronomy. "Many doubted whether it was practical to trade off the cost of a single, large primary mirror against the complexity of the control and alignment systems needed to operate a number of smaller mirrors simultaneously. And even if the trade-off proved to be worth it, there were doubts about whether the control system could be made to work adequately—and to run routinely."

Some of these reservations—and in particular the last one—have yet to be answered. But preliminary viewings have already been successful, even

though the telescope has to be operated manually until the computerised control system is linked up. Professor Hoffmann says he does not foresee any major problems.

There are three radical innovations in the MMT design, each of which is being closely followed elsewhere as suggestion new directions in telescope construction. The MMT is really a combination of six parallel Cassagrain telescopes, each with its own 1.8-metre primary mirror and its own secondary mirror, with the separate images focused to a single point. This results in a light collecting capability equivalent to a 4.5-metre telescope—still behind the 5-metre telescope on Mount Palomar and the Russian 6-metre telescope, but its compact design means that, at \$7.5 million (in 1975 prices), the MMT cost less than a third of a conventional design.

Laser beams align the mirrors, using the MMT's guide-alignment telescope as a collimator for a laser-generated point source. The beam is split into six components, each used to keep a check on one of the mirrors and control its fine-adjustment mechanisms. "The problem is comparable to getting six headstrong ballerinas to dance as if they were one," says one of the project directors.

MMT may well serve as a prototype for a new generation of optical telescopes, avoiding the increasingly prohibitive costs of large primary mirrors. Already a multi-mirror design is being considered as one option for a 10-metre telescope being planned by the University of California. Scientists at the neighbouring Kitt Peak National Observatory are exploring a similar approach to a 25-metre instrument.

The second design innovation is the

Complex of steel girders hides the mirrors

mounting. Most conventional telescopes use an equatorial mount, meaning that movement about only one axis is required to compensate for the rotation of the Earth. The MMT, in contrast, uses an alt-azimuth mount, the horizontal axis being provided by a large steel yoke which itself turns on a vertical axis. Keeping track of an object during viewing means rotating the telescope about both axes simultaneously, a process which is controlled by a special mini-computer.

Both the compact design of the telescope, and the alt-azimuth mounting, led to the concept of a rectangular housing. "Any dome is, in its own geometry, azimuthal, but with an equatorially-mounted telescope you need the extra swing-space within the dome," says Professor Hoffmann. "With the alt-azimuth mount, motion is either up and down or circular, so saving space inside the dome is no longer necessary. A rectangular space then became much more convenient than a spherical one."

Professor Hoffmann says that although when first suggested the fork mounting and the rectangular building were considerable innovations, it turned out to be so practical that he thinks "people will soon find that the hemispherical dome and the equatorial mount are no longer attractive". Scientists from the Australian National University are already contemplating using this approach for a new telescope on Mount Stromlo, and others are expected to follow.

When it becomes fully operational, the MMT, which will be able to operate in both visible and infra-red parts of the spectrum, will have a number of uses. It will be able to carry out infra-red photometry that could help scientists identify materials on the surface of Pluto and the satellites of Uranus and Neptune, and also provide detailed measurements of highly red-shifted optical spectral lines from distant quasi-stellar objects.

Another major application will be in spectroscopy. By projecting the images from the six main mirrors along a line, rather than on to a single spot, the MMT will be able to compensate for the light lost when the single image from a conventional telescope is focused on a single slit.

With other ground-based facilities—particularly those at Kitt Peak—increasingly in demand, there will be no shortage of users for the MMT. "They are already beating a path to our door," says Professor Hoffmann. Initial users will be those from the Smithsonian and the University of Arizona. Subsequently, applications for experiments will be open to all comers. □

# 'North' meets 'South'—without the bickering

**Roger Revelle** reports on hopes for a new era of scientific and technical cooperation in the Third World

FOR a variety of reasons, including the probable makeup of the national delegations, the United Nations Conference on Science and Technology for Development (UNCSTD) to be held in Vienna in August, will be largely political and diplomatic.

So to provide a forum for scientists and engineers to express their ideas for UNCSTD, the International Council of Scientific Unions (ICSU) enlisted the cooperation of other international professional organisations (including those of the social scientists, humanists, physicians and engineers, and such quasi-scientific groups as the Club of Rome and Pugwash), in sponsoring an International Symposium on Science and Technology for Development, which was held in Singapore during the week of 22 January under the chairmanship of Thomas Malone, Treasurer of ICSU and Foreign Secretary of the National Academy of Sciences. Some 120 natural and social scientists and engineers from forty countries participated, besides observers from the United Nations and its specialised agencies, and from national technical assistance organisations. More than half the participants came from the developing countries of Africa, Asia, and Latin America, while the remainder represented both the capitalist and the 'centrally planned' industrialised countries. Notably absent were representatives of the People's Republic of China—which has had difficulties with ICSU over Taiwan—and the oil-rich Arab countries, though scientists from Egypt, Sudan and Morocco actively participated.

Thomas Malone

Some of the more important conclusions of the symposium were:

- The application of science and technology for development depends very largely on the existence of effective scientific and technical institutions within each developing country. Through these, each country can improve its indigenous technology,

make rational choices among foreign technologies, absorb chosen technologies, and create new ones appropriate for its special circumstances. These institutions will need to conduct some basic and applied research, as well as technological development, in order to retain a competent staff and to stay aware of scientific advances throughout the world that may eventually become useful to their country.

- To build up their scientific and technical capabilities and their industries, the developing countries require a greatly increased corps of qualified technicians and other skilled workers. A large number of technical schools and junior colleges should thus be established in the Third World, and should be open to both sexes to expand employment opportunities for women. Apprenticeship training for LDC technicians in the industries of the developed countries and in multinational corporations in their own countries should be strongly encouraged, while school curricula in science and technology need expansion and modernisation, with emphasis on experimental work and manipulation of equipment.

- The establishment of regional research and development institutions (analogous to the present international agricultural research centres) should be considered, covering a wide range of scientific and technical fields, including forestry, fisheries, management of land and water resources, construction, transportation, and industrial technology. These regional institutions will need to work closely with the national research and development agencies, to ensure the results of their research are put to practical use.

- More donor agencies concentrating on support of research and development in and for the Third World, like the International Development and Research Centre (IDRC) in Canada, the Netherlands University Foundation for International Cooperation (NUFIC), the Swedish Agency for Research Cooperation with Developing Countries (SAREC), and the Deutsche Gesellschaft für Technische Zusammenarbeit (GTZ) should be established

in the industrialised countries. Existing agencies should be encouraged to co-operate more closely with each other in exchanging information and ideas and in creating interacting programmes. The outstanding work of the International Foundation for Science and the United Nations University, in supporting applied research by LDC scientists within their own countries, deserves greater financial backing by the developed countries.

- Physical and biological scientists and engineers in the developed countries need to be more aware of the developing countries' underlying problems, whose solution demands both basic and applied research; they should be encouraged to undertake such research in cooperation with scientists from the Third World. For this purpose, the international scientific organisations need increased participation by scientists of the developing world, and improvements in their analysis and communication in areas related to developing country problems. UNESCO and other specialised UN agencies could help the non-governmental organisations play a more effective role. International 'workshops' focused on specific problems, in which scientists from developed and developing countries jointly formulate research and development programmes, can serve as a catalyst for cooperative efforts.

One distinguishing aspect of the symposium was the range of talent, experience and knowledge among the participants; another was the absence of the harsh confrontations between the "North" and the "South" that have frustrated useful discussion in many recent UN-sponsored conferences. Instead, it seemed clear at Singapore that a new international scientific and technical order is an essential prerequisite for the new international economic order so earnestly desired by the countries of the Third World.

The symposium considered ways in which science and technology could be used to alleviate some of the most critical developing country problems. The real incomes of the poorest classes need to be increased, by reducing unemployment and increasing productivity by means of appropriate rural and urban industries, which can be created through applied research, or by adaptation of existing technology to utilise available resources. But technical and managerial skills in the rural and urban labour forces must also be developed, and the tools of the social scientist must be used as a guide to choices of industrialised technology.

These industries will require considerable increases in energy supplies, particularly in rural areas, and hence the development of new sources of energy and new means for energy conservation. The energy problem is also related to the need to increase and diversify agricultural production, to develop forest resources and to improve transportation.

Natural and social scientists must also work together to bring about the social and economic improvements in health that will help to slow down population growth and ultimately stabilise the size of populations.

Throughout the symposium, special emphasis was given to the role of women in the development process, in particular the need for greatly expanding women's opportunities for employ-

ment and education, and for relieving the unallayed drudgery that characterises traditional 'women's work' in rural societies. The unfavourable socioeconomic environment for women would be improved if they could participate more fully in development—the less-developed countries cannot reap the full benefits of technology until this vital human resource has been mobilised. Conversely, the multiple impacts of technology on the welfare of women in changing societies must be evaluated.

Industrialists in both developed and less-developed countries will inevitably have a central role in the application of science and technology to development. To serve their own long-range interests, industries operating in each developing country should be en-

couraged to choose technologies and a scale of operations that are most appropriate for the local factors of production and lead to greater equity within the country, as well as improving the human and natural-resource base.

The participants were unanimous in agreeing that the Singapore symposium should not be an isolated event. A continuing steering committee was established which has begun to explore those problem areas that could be most effectively approached by cooperation among scientists and technologists from the rich and the poor countries. □

## UNCSTD: gloom over growing gulf between politicians and scientists

"THE gap between the 'experts' and the policy-makers, between those who study and work with science and technology, and those who make development decisions—that gap seems to be growing ever larger as UNCSTD draws near", laments the latest issue of the *Lund Letter*, a Swedish commentary on preparations for the conference.

And a recent Swedish Royal Academy of Sciences meeting has emphasised the point. Called to inform and stir up interest among scientists who may not have been involved in the official preparations for the conference, the day-long discussions left a pessimistic impression of what the official UNCSTD session can hope to achieve.

The non-governmental organisations, however, offer more hope. They came up with some good ideas at their meeting in Singapore in January (see above), and the academy meeting pointed to several areas where Swedish research could be useful to the Third World. The non-governmental organisations seem certain to make a hefty intellectual and psychological contribution.

One suggestion for a new form of cooperation came from Dr Stephan Schwartz, the head librarian at the Royal Institute of Technology, who wanted to improve the flow of scientific and technical information to developing countries. From his own survey of the age distribution of references in scientific journals, it is apparent that in a good journal (*Nature* was his example), half of the references are less than two years old. In a journal used in even a relatively advanced developing country like Portugal, half the references are seven to 10 years old.

This means that the Third World is not getting the most up-to-date information, and is therefore not able to tackle its problems in the most up-to-

date ways. This situation could be improved by establishing link-ups between libraries in developing countries and Western institutes which could do computer searches of the specialised literature needed to cope with the countries' particular problems. Photocopies of most important material could then be supplied to the developing countries.

Dr Schwartz pointed out, however, that the information such a system could supply would be useless unless it could be assimilated by the local science and technology system. He thus echoed one of the meeting's recurrent themes: that development of one sector in a country is only possible if it is backed up by development in all the other sectors. It is these gaps that are hardest to close, because they are the result of development and depend on all other gaps closing first.

The gaps in the politicians' outlooks are so wide as to make them incompatible. In agriculture alone, Asian and African demands are totally different from what the Europeans want to offer.

As Mr Thomas Rosswall from SCOPE (the Scientific Committee on the Problems of the Environment, set up by the International Council of Scientific Unions) pointed out, the European Community (EC) paper presented to UNCSTD's Third Preparatory Committee in January maintains that it is possible, with adequate water and fertiliser supplies, to triple and quadruple yields from traditional varieties of seeds. This is irrelevant to the Third World, where neither adequate water supplies nor fertilisers are available.

In talking about the advantages of fertilisers, the EC paper takes no heed of the fact that widespread use of fertilisers is only possible where their cost, relative to the costs of other agricultural inputs, is low, which is certainly not the case in developing

countries. Again, the EC paper, recounting the European experience, sees mechanisation as a good way of achieving economies of labour. But the Asian and African papers specifically say that they want labour-intensive agricultural systems.

On a more practical note, Dr Bo Hall, of the Department of Agriculture's Commission on Natural Resources, pointed to research on the production of pig iron on a small scale but at prices competitive with the iron produced from big blast furnaces. Small-scale methods are needed for the exploitation of small domestic markets, in contrast to the large-scale technologies developed by the multinationals for developing large ore bodies.

Dr Malin Falkenmark, of the Natural Sciences Research Council's Committee for Hydrology, said that research on groundwater in hard rock is a Swedish speciality and could be useful in India and West Africa especially, where rock groundwater is an important source of water. Groundwater replenishment techniques—techniques for artificially recharging groundwater supplies—were originally developed in Sweden and could probably be used widely in arid and semi-arid areas.

There are vast regions where Swedish work on erosion and sedimentation could also be applied. These processes are not always thought of in relation to river basin development, although many reservoirs rapidly fill up with sand if erosion is not stopped on lands further upstream. Finally, the Nordic countries could pool their work on water assessment—determining the available water resources in an area to avoid over-exploitation—and help developing countries to make water assessments of their own.

## Jobs: the need to reach an ideal steady state

SIR,—The problem of short-term contract workers is a serious one but it is also very complex and one should beware of facile solutions which can have even more disastrous long term repercussions.

To illustrate the problem one has to look at the ideal steady state. In the biomedical sciences we estimate that there are about 5,000 tenured academic and research posts in United Kingdom Universities and research institutes. There is probably about the same number in the physical sciences. Since each tenured post is occupied for about 35 years the average turnover rate, assuming no wastage, should be about 2.8% per annum. With a uniform age distribution, we could expect 130 vacancies every year in the biomedical sciences simply for renewal. It would mean that we could have a total of 400 people in three year postdoctoral fellowships with excellent chances of their being placed in tenured posts at completion.

The problem is that we are very far from this situation. In 1976, only 20% of the science posts in British universities had holders aged 50 and above, which means that for the next 15 years the retirement rate is going to be about 1% and we can only expect positions to appear about  $\frac{1}{4}$  of that expected from the ideal steady state. Thus the biomedical sciences will only have about 30 to 40 vacancies a year which not only accords more with what we know to be the case, but also tells us that this will be with us to very near the end of the century. The reasons are obvious; this generation is now paying the price for the rapid change in the rate of expansion in the late fifties and sixties; the people they are replacing were appointed before that when the system was much smaller. It is also easy to see that if the step at the below 40 age group is followed by a trough, the long term consequences could be disastrous.

The only solution is to aim to get to the ideal steady state position now. Tenured posts must be offered in universities at the average turnover rate, but in order to do this the system will have to undergo an absolute expansion. Naturally this bulge should not enter into the calculation of the turnover rate, but should be seen only as a borrowing against future vacancies. It seems to me that, in the main, this has to be done largely by government intervention as part of a deliberately planned policy. Nevertheless, there are contributions which might be made by private foundations and possibly by research councils. The best they could do would be to create senior research positions in universities for people already holding university posts. These would all be *ad hominem* appointments so that the subject areas and the candidates are selected by these organisations, and the posts are not simply given away with no control. However, the position vacated by such an appointment can now become available to the university for a new entrant. In essence, in this scheme, the outside organisation is only temporarily

committing itself to a university for the length of tenure of the post, perhaps 15 years; for new tenured entrants, the commitment is for 40 years and only the universities can do that.

From this analysis it can be seen that temporary posts do not help, except as offering some small buffering capacity. They can only be created and used effectively against future vacancies, and unless accompanied by other actions they can only worsen the situation. A prolonged postdoctoral period can be seen as a mechanism which gives the occupants several additional opportunities to apply for permanent posts as they arise annually. This does not help as long as the input further back in the system provides excessive competition, and the difficulties are further compounded by the universities choosing younger candidates for lectureships because they are cheaper than the man with several years experience. We have also to tackle the question of the number of people doing PhD degrees, and this raises a whole new set of problems. What is a PhD degree for? If it is seen as the first step towards a research or academic career, and this is the expectation of people doing it, then we are producing too many, and the numbers should be cut. Universities would strongly oppose that step, because PhD students provide a cheap source of research labour in many university science departments. We have to look at postgraduate education and training as a matter of urgency; it is clearly impossible and undesirable for every university to have a graduate school in every subject, since that puts demands on resources that cannot be met.

The question of the short-term workers is only the tip of the iceberg and the central problems are deepseated and long term. In some way, everybody involved needs to be got together to find a national solution; and unless this is done soon and in a concerted manner I, for one, am very nervous about the long term future for British science and higher education.

## Little danger from radon

SIR,—Recently, *Nature* reported (30 November 1978, page 431) the work of Berkeley scientists who have expressed concern that reduced ventilation rates may increase the hazard from the inhalation of the short-lived daughters of  $^{222}\text{Rn}$ . This problem has been under consideration by the National Radiological Protection Board in recent years and we think that the conclusions reached by the workers at Berkeley should be approached with caution.

They based their case on extrapolation from uranium miners' medical data. For uranium miners, W. Jacobi (Proceedings of NEA Specialist Meeting, Elliot Lake, Canada, OECD, Paris pp. 33-38; 1977) has estimated 200 excess lung cancer deaths among a population with a cumulative exposure of  $10^6$  Working Level Months. (The Working Level Month

**Table 1** Lung cancer incidence predicted due to environmental radon daughter exposure

Winter ventilation rate $\text{h}^{-1}$	Mean population exposure WLM $\text{y}^{-1}$	Lung cancer cases predicted per $10^6$ population per year
0.8	0.15	30
0.5	0.22	44
0.4	0.28	56
0.3	0.38	76
0.2	0.58	116
0.1	1.15	230

(WLM) is 170 hours exposure at 1 Working Level (WL); the Working Level is a measure of the concentration of the potential alpha energy in air from any combination of the short-lived daughters of radon.  $1 \text{ WL} = 1.3 \times 10^8 \text{ MeV m}^{-3}$ . A recent survey (Cliff, K. D., *Phys. Med. Biol.* 23, 696-711; 1978) estimated that the average population exposure rate domestically to radon daughters for Great Britain is about 0.15 WLM per year.

From the above figures it is possible to deduce, for the female population of Great Britain (assuming a 20 year latency period) that inhalation of radon daughters has caused more bronchus and lung cancer deaths up to the age of 40 than actually occur from every single cause, according to mortality statistics. This result shows the danger of applying a risk estimate derived from a special group to other groups of the population. Even if allowance were made for more rapid room ventilation in the days of open fires, we would still deduce that lung cancer incidence among women under 40 was entirely attributable to radon, and that smoking made little contribution—an untenable conclusion.

Is a WLM to a working miner the same, from a comparative dosimetry point of view, as that to a member of the general population? Studies show that, to within a factor 2, there is no difference in the deposition of radon daughters in the lung. In the absence of any other data, apart from that for miners, on which to base a risk estimate for the general population we may use Jacobi's figure to consider the implications of a general reduction in ventilation rates during winter. We assume a mean ventilation rate in summer (5 months) of two room changes per hour and that energy conservation efforts will not alter this rate. Table 1 shows the predicted incidence of lung cancer in the population (male and female) of Great Britain as the mean winter (7 months) ventilation rate is reduced. The current total lung cancer incidence in Great Britain is about 650 per  $10^6$  population per year.

It cannot be stressed too strongly that such calculations as given in Table 1 should be regarded as speculative and represent an absolute upper limit to possible lung cancer incidence attributable to environmental radon daughter concentrations.

## Clinical relevance of opiate receptor and opioid peptide research

from Solomon H. Snyder

OPIATE receptors<sup>1</sup> and the enkephalins, their endogenous peptide ligands<sup>2</sup>, have advanced the understanding of numerous brain functions and provided several potential clinical applications.

The localisation of opiate receptors as revealed in the elegant autoradiographic studies of M. J. Kuhar<sup>3</sup> has clarified the neuronal sites at which these drugs exert their pharmacological effects. Opiate overdose causes death by depressing respiration. High densities of opiate receptors in the nucleus of the solitary tract, a respiratory reflex centre, suggest likely sites of this activity. Opiates constrict the pupils, accounting for the 'pinpoint' pupils of heroin addicts, an effect apparently attributable to opiate receptors in the pretectal nuclei. Opiate receptor concentrations within the limbic system may mediate euphoric effects. If opiate receptors vary in drug specificity throughout the brain, as suggested by pharmacological data<sup>4</sup>, novel drugs acting selectively on individual receptor populations might afford selective therapeutic advantage.

### Opiate addiction

The opiate receptors which are highly concentrated in the locus coeruleus may have direct relevance for treating opiate addicts, especially their withdrawal symptoms. Though the locus coeruleus contains only 1,400 neuronal cells, all contain noradrenaline and their axons project ubiquitously, providing the major adrenergic innervation of the central nervous system. Micro-injections of opiates selectively inhibit firing of locus coeruleus neurones but fail to alter the activity of closely adjacent cell groups which do not possess opiate receptors<sup>5</sup>. Besides opiate receptors, locus coeruleus cells also possess  $\alpha$ -adrenergic autoreceptors, whose stimulation by noradrenaline or clonidine, which mimics noradrenaline at  $\alpha_2$ -receptors slows their firing<sup>6</sup>. Mor-

phine tolerance and physical dependence in rats is accompanied by tolerance of the locus coeruleus to the slowing effects of opiates but not of clonidine<sup>6</sup>. Opiate withdrawal in these rats elicits extremely rapid firing of locus coeruleus neurones.

Drugs which block the  $\alpha_2$ -adrenergic receptors, such as piperoxane and yohimbine, accelerate the firing of locus coeruleus neurones and produce subjective effects of anxiety and agitation as well as hypertension in humans. As these symptoms resemble opiate withdrawal, some abstinence symptoms might result from enhanced locus coeruleus activity. If this were the case, drugs slowing locus coeruleus neuronal firing might alleviate opiate withdrawal symptoms. Gold *et al.*<sup>7</sup> observed a dramatic alleviation of abstinence symptoms in human methadone addicts treated with clonidine. Thus, clonidine or related agents may prove useful treatments for opiate withdrawal. Conceivably, maintenance therapy with such drugs would ease the craving of addicts for heroin.

### Developing new analgesics

Simple test tube assays to measure opiate receptor binding have greatly facilitated the screening of potential new opiate-related drugs. More important, the discovery that low concentrations of sodium ion selectively differentiate the actions of agonists, antagonists and mixed agonist-antagonists at opiate receptors may facilitate development of potentially less addictive opiates<sup>8</sup>. Sodium 'weakens' the binding of pure agonists to opiate receptors by 15–100-fold, while not influencing the binding of pure antagonists at all. Drugs with both agonist and antagonist activity are affected in an intermediate fashion. Before biochemical labelling of the opiate receptor these mixed agonist-antagonist analgesics, which have reduced addictive potential, were difficult to detect by tests in intact animals. Opiate receptor screening has simplified their identification. Until recently, pentazocine (Talwin) was the only mixed agonist-antagonist opiate available

commercially. Though less addictive than conventional opiate agonists, pentazocine does not relieve severe pain as well as does morphine. At therapeutic doses pentazocine sometimes elicits anxiety, depersonalisation and psychotomimetic effects. A 'second generation' of mixed agonist-antagonist opiates are now appearing on the market. Butorphanol (Stadol), from the same benzomorphan class as pentazocine, is more potent and might conceivably have fewer psychotomimetic effects. Nalbuphine and buprenorphine are very promising mixed agonist-antagonists which may have even greater potential, but are not yet widely enough used to judge their liability to cause addiction.

### Enkephalin analogues

Numerous pharmaceutical concerns have developed enkephalin analogues for possible therapeutic uses, hoping that derivatives of such a natural substance might be non-addicting. The amino acid sequence of Met-enkephalin is tyrosine-glycine-glycine-phenylalanine-methionine, while Leu-enkephalin differs from Met-enkephalin simply by the substitution of a carboxyl-terminal leucine for methionine. Replacement of the glycine at position 2 by D-alanine greatly reduces the proteolytic susceptibility of enkephalin. Other modifications increase receptor affinity, facilitate penetration of the blood-brain barrier, and enhance absorption from the gastrointestinal tract. The Sandoz Company reported a pentapeptide FK-33824 which differs from Met-enkephalin only in the replacement of glycine-2 with D-alanine, the N-methylation of phenylalanine and alteration of the methionine by oxidising its sulphur to a sulfoxide and conversion of the carboxyl to a carbinol<sup>9</sup>. This drug is 30,000 times more potent than enkephalin when injected into the brain, is an active analgesic when administered parenterally and orally and has already been evaluated in humans<sup>10</sup>. The facial flushing produced by FK-33824 resembles the naloxone-reversible facial flushing in

Solomon H. Snyder is Distinguished Service Professor of Pharmacology and Psychiatry, Departments of Pharmacology and Experimental Therapeutics and Psychiatry and Behavioral Sciences, Johns Hopkins University School of Medicine, Baltimore.

some diabetics given the anti-diabetic drug chlorpropamide followed by alcohol, implicating enkephalin in the pathophysiology of certain types of diabetes<sup>11</sup>. In some animal tests, FK-33824 elicits physical dependence, but is less 'addictive' relative to its analgesic activity than are conventional opiate agonists (D. Romer, personal communication). A possible successor to FK-33824 has already been developed simply by adding an N-methyl group to the tyrosine<sup>12</sup>. The resultant methyl-FK-33824 is five times more potent than FK-33824 by subcutaneous injection and orally. Its oral form is equipotent with morphine.

The Lilly Pharmaceutical Company has developed an enkephalin analogue differing from 2-D-alanine-Met-enkephalin simply by methylation of methionine's amino nitrogen and conversion of methionine to an amide. This agent, LY-127623 seems to have similar potency to FK-33824 (refs 13, 14) when administered parenterally but is less active when given by mouth.

LY-127623 may be less addictive. Withdrawal symptoms in morphine-addicted rats are much less severe with LY-127623 than with other conventional opiate agonists or mixed agonist-antagonists examined. Also, at equi-analgesic doses LY-127623 produces less respiratory depression than morphine. In numerous pharmacological tests LY-127623 and FK-33824 behave

like pure opiate agonists. Thus these enkephalin analogues may be unique as agents outside the mixed agonist-antagonist group with reduced propensity to cause addiction. The absence of direct comparisons between LY-127623, FK-33824 and other enkephalin analogues precludes conclusions about their comparative benefits.

Drugs which inhibit enzymes that inactivate endogenous substances are often powerful therapeutic agents—for example, acetylcholinesterase and monoamine oxidase inhibitors. Enkephalin can be degraded by a wide range of nonspecific peptidases. Recently Malfroy *et al.*<sup>15</sup> identified a specific 'enkephalinase' in brain membranes. This enzyme has a much greater affinity for enkephalin than for most other peptides. Its regional distribution throughout the brain resembles that of the opiate receptor. Moreover, in rats chronically treated with morphine, enkephalinase activity increases substantially, while other peptidases show no change. Drugs which facilitate enkephalin action by blocking this enzyme might have unique applications extending beyond the opiate field. Enkephalinase seems closely similar to the angiotensin-converting enzyme which transforms the inactive angiotensin I to the physiologically active angiotensin II<sup>16</sup>. This same enzyme also inactivates bradykinin, a peptide which regulates inflammation, vascular shock and pain perception. Bradykinin has recently been localised to specific neuronal systems in the brain<sup>17</sup>. Thus, enkephalinase inhibitors might influence bradykinin and angiotensin as well as

enkephalin.

A role for opioid peptides in mental illness was suggested by preliminary reports of a beneficial effect of the pituitary peptide  $\beta$ -endorphin in schizophrenic and depressed patients<sup>18</sup> and reduced auditory hallucinations in schizophrenics treated with naloxone<sup>19</sup>. These findings emerged from uncontrolled studies and await full confirmation in double-blind placebo-controlled experimental designs. Support for effects of opioid peptides in schizophrenia emerges from the positive influence of FK-33824 on hallucinations and overall mental state in a study of eight patients in Denmark<sup>20</sup> and in six schizophrenics in Munich (N. Nedopil & E. Ruther, personal communication). In the Danish study patients received intramuscular injection of 1, 2 and 3 mg on three successive days, while in the German study 0.5 mg and 1.0 mg were given in intravenous infusions on two successive days. Unfortunately, neither of these studies was conducted in a double-blind fashion.

One controlled study suggests beneficial effects in schizophrenia of an opioid-related peptide which has no opiate activity. [Des-Tyr<sup>1</sup>]- $\gamma$ -endorphin comprises amino acids 62–77 of the pituitary peptide,  $\beta$ -lipotropin. The absence of an N-terminal tyrosine abolishes affinity for opiate receptors. On the basis of its behavioural effects in rats<sup>21</sup> [des-Tyr<sup>1</sup>]- $\gamma$ -endorphin was administered to chronic schizophrenics<sup>22</sup>. In a double-blind placebo-controlled crossover design the peptide in daily doses of only 1 mg dramatically alleviated schizophrenic symptoms. □

## Prostacyclin in blood vessel-platelet interactions: perspectives and questions

from Philip Needleman

BLOOD vessels possess the capacity for the intrinsic synthesis of vasodilator prostaglandins, thereby providing considerable potential for the local regulation of vascular tone<sup>1</sup>. Prostacyclin<sup>2,3</sup> or its stable metabolite 6-keto-PGF<sub>1 $\alpha$</sub> <sup>4,5</sup> is the primary vascular prostaglandin produced. As prostacyclin (PGI<sub>2</sub>) is a potent inhibitor of platelet aggregation *in vitro*<sup>6</sup> it thereby became a prime candidate for the local vascular regulation of thrombotic events.

Isolated blood vessel preparations rather inefficiently (<5%) convert exogenous arachidonate (by way of the enzyme cyclooxygenase) into prostacyclin.

Philip Needleman is Head of Pharmacology, Washington University Medical School, St Louis, Missouri.

glandin endoperoxides. However, the prostacyclin synthetase in vascular tissue quantitatively (>80%) metabolises exogenous or endogenous PG endoperoxides into PGI<sub>2</sub>. On the other hand, platelets possess a very active cyclooxygenase which readily cyclises arachidonate into endoperoxide which is then enzymatically converted into the potent aggregator and blood vessel constrictor, thromboxane A<sub>2</sub>. Bunting *et al.*<sup>6</sup> and Moncada *et al.*<sup>7</sup> found that blood vessel segments treated with indomethacin (a reversible cyclooxygenase inhibitor) and stirred with platelet-rich plasma, prevented aggregation in mixing experiments. They therefore proposed the hypothesis that endoperoxides are released from platelets during aggregation and are used by

the blood vessels to synthesise prostacyclin. Such an exchange of products simultaneously bypasses the inefficient vascular cyclooxygenase and deprives the platelets of substrate for thromboxane synthesis. An implication of such an interaction is that thrombosis and vascular tone may be mediated or modulated by the local balance of the ratio of vascular-prostacyclin/platelet-thromboxane.

An understanding of platelet and blood vessel arachidonate metabolism and interactions has therefore become the focus of considerable research. In this issue of *Nature* (page 66), Hornstra, Haddeman and Don report data which demonstrate that unstimulated or collagen-activated platelets do not seem to release endoperoxides which could be used as substrate for PGI<sub>2</sub> synthesis by vascular fragments. They also observe that indomethacin inhibition of the aortic cyclooxygenase was reversible, and that intrinsic vascular PGI<sub>2</sub> was the culprit that inhibited the platelets in mixing experiments. We recently demonstrated<sup>8</sup> that exogenous [<sup>14</sup>C]-arachidonate added to intact human platelets in the presence of blood vessel microsomes (as a source of prostacyclin synthetase), resulted in the production of [<sup>14</sup>C]-thromboxane B<sub>2</sub> only. PG endoperoxides were released from the intact platelets only when thromboxane synthesis was inhibited by imidazole (an antagonist of thromboxane synthetase *in vitro*); the blood vessel microsomes converted the released endoperoxide into PGI<sub>2</sub>. Furthermore, incubation of unstimulated or thrombin-activated human platelets which contain [<sup>14</sup>C]-arachidonate-labelled phospholipids, with aspirin-treated intact aorta, immediately resulted in adhesion. The only cyclised arachidonate product of this platelet-blood vessel adhesion reaction was labelled thromboxane, while no labelled 6-keto-PGF<sub>1α</sub> was detectable. However, thrombin stimulation of imidazole-inhibited platelets resulted in the release of platelet-derived labelled PG endoperoxides which were converted to labelled PGI<sub>2</sub> by the vascular prostacyclin synthetase. Comparable results have been obtained by Baenziger *et al.*<sup>9</sup> (*Cell* in the press) who incubated cultured human arterial smooth muscle

and venous endothelial cells with human platelets in the presence of arachidonate and measured PGI<sub>2</sub> production by bioassay (that is, inhibition of [<sup>14</sup>C]-serotonin release from platelets). Significant prostacyclin synthesis from platelet-derived PG endoperoxides by cultured cells pretreated with aspirin was observed only when platelet thromboxane synthesis was inhibited. All these results mitigate against the attractive notion that blood vessels derive endoperoxide from platelets for subsequent conversion to PGI<sub>2</sub> and are thereby protected from deposition of platelets on vessel walls. Fortunately, however, these experiments have unmasked a pharmacological strategy which may enable one to manipulate the platelet-blood vessel interaction to improve the local prostacyclin/thromboxane ratio. This might be useful therapeutically in thrombosis, coronary and cerebral vasospasm and perhaps atherosclerosis. Development of a thromboxane synthetase inhibitor effective *in vivo* could facilitate the release of platelet endoperoxide on which vascular prostacyclin synthetase could then act. As vascular injury initiates platelet adhesion and aggregation, a thromboxane synthetase inhibitor has the potential selectively to generate prostacyclin right at the critical site.

Despite the demonstration of a fascinating range of pharmacological effects, the physiological and pathological role of vascular prostacyclin production and its effect on platelet function still needs considerable clarification. For example, it was initially suggested that vascular endothelial cells were the primary vascular source of the anti-thrombotic PGI<sub>2</sub>, and loss of endothelium during injury, therefore, favoured local thrombosis<sup>10</sup>. However, subendothelial vascular smooth muscle readily produces prostacyclin under conditions which favour thrombosis<sup>11</sup>. It is difficult to reconcile the synthesis of PGI<sub>2</sub> by blood vessels with damaged endothelium with the idea that PGI<sub>2</sub> is one of the chief deterrents of thrombosis.

Another thought-provoking platelet-blood vessel interaction was recently reported in *Nature* by Gryglewski *et al.*<sup>12</sup> and Moncada *et al.*<sup>13</sup> Their discovery suggests that prostacyclin might be continuously synthesised by the lungs and released as a circulating hormone into the arterial blood. However, the actual PGI<sub>2</sub> levels present in the arterial blood must be ascertained in more physiological circumstances. In the above studies the demonstration of arterial PGI<sub>2</sub> levels was in anaesthetised heparinised animals in which the blood was recirculated through a peristaltic pump. By analogy, previous experience with intact animals has demonstrated that high levels of renal pro-

staglandins are produced in anaesthetised, surgically prepared dogs, whereas little if any renal PG production occurs in unanaesthetised trained animals. Indeed, if PGI<sub>2</sub> is circulating in high enough concentrations to interfere with platelet aggregation, then platelet cyclic nucleotide concentrations should be raised in freshly prepared platelet-rich plasma, which is not the case. Furthermore, it should be possible to demonstrate circulating levels of 6-keto-PGF<sub>1α</sub> (by immunoassay and mass spectrometry for example) in blood drawn from anaesthetised experimental animals or man. The resolution of some of these intriguing questions may help to clarify the physiological and pathological role of intrinsic prostacyclin synthesis in regulating platelet function. □

## Iron storage in bacteria

from Pauline M. Harrison

ENTERIC and other bacteria have been known for some time to synthesise low molecular weight siderophore molecules of high iron affinity, which enable them to scavenge the iron they require from the medium, even when it is present in low concentration. The bacteriostatic effects of the iron-carrier in serum, transferrin, and of similar molecules in milk and in egg-white may be due to competition by these molecules with the siderophores for iron. Synthesis of siderophores is regulated by negative feedback mechanisms, which shut off their synthesis when iron is abundant. The need for a means of storing iron in bacteria has not been apparent and until recently no counterpart has been found of the iron-storage molecule, ferritin, which occurs in a variety of eukaryotic species from fungi to man. Now ferritin, or a ferritin-like molecule, has been found in several bacterial species. The molecule characterised by Stiefel and Watt (this issue of *Nature* page 81) as a bacterioferritin was first isolated from the nitrogen-fixing bacterium *Azotobacter vinelandii* by Bulen and coworkers (*Biochem. biophys. Res. Commun.* **54**, 1274; 1973) who described the molecule as a *b*-type cytochrome containing large amounts of non-haem iron and no labile sulphide. Stiefel and Watt now show that this molecule is not only a haem protein, but closely resembles mammalian ferritin in several respects. The combination of both types of iron within a single molecule is most unusual and is not known in ferritins

of higher organisms. To what extent then are Stiefel and Watt justified in designating their molecule a bacterioferritin?

Ferritin from animal or plant sources is a molecule of potentially high but variable iron content (up to at least 30% by weight or over 4,000 Fe atoms per molecule) held within a protein shell. Its iron is in the form of 'micelles' or microcrystals of hydrous-ferric-oxide-phosphate, which can be seen in the electron microscope without staining or shadowing as particles of about 60 Å diameter. This property of ferritin enables it to be recognised within cells and it has been used as a marker for other molecules tagged to it. It has been shown in several species that iron stimulates the biosynthesis of ferritin: protein subunits assemble to form shells, which accumulate iron. A recent high resolution electron density map of horse spleen apoferritin (Banyard, Stammers & Harrison *Nature* **271**, 282; 1978) shows the molecule as a symmetrical assemblage of 24 subunits each of 18,500 molecular weight with high helix content giving an outer diameter of 130 Å. The structures of several other crystalline ferritins are very similar, but some animal and plant ferritins may be larger. Mössbauer spectroscopy of horse spleen ferritin provides evidence of anti-ferromagnetic ordering within the iron cores at low temperatures, the ordering temperature depending on iron content and particle size.

The 'bacterioferritin-cytochrome' of Stiefel and Watt has an iron content of 13–20% by weight, a subunit weight of 17,000, a molecular diameter comparable to that of animal ferritin and an electron-dense core of 55 Å. Its magnetic susceptibility and temperature-dependent Mössbauer spectra establish it as containing weakly-coupled high-spin  $\text{Fe}^{\text{III}}$  reminiscent of ferritin iron. However, the presence of protoporphyrin IX (one per two protein subunits) is distinctive and the potential required to reduce both forms of iron is more negative than that for horse spleen ferritin. Moreover, the bulk of the  $\text{Fe}^{\text{II}}$  is retained inside the molecule on gel filtration, whereas it is more readily lost from the horse spleen protein, presumably diffusing out of the molecule through channels in the protein shell seen in the electron density maps. Stiefel and Watt have considered the possibility that their 'bacterioferritin' may act as an electron store or as a specific iron-storage depot for the iron-containing

protein nitrogenase.

At a recent meeting on Proteins of Iron Metabolism\* Bauminger, Cohen, Levy, Ofer and Yariv of the Hebrew University, Jerusalem, described evidence for the presence of a new type of iron-storage compound in *E. coli* grown on  $^{57}\text{Fe}$ -enriched media. Mössbauer spectra of packed cells showed the presence of high spin  $\text{Fe}^{\text{III}}$  with evidence for magnetic ordering below 2.6 K. An iron-rich protein, of approximately 300,000 molecular weight containing electron-dense particles was isolated and gave Mössbauer spectra similar to those of the whole cells, but this soluble protein accounted for only about 1% of the iron content of the whole cells grown on the most iron. These workers consider the pure protein from *E. coli* to be quite distinct from ferritin. They report similar  $^{57}\text{Fe}$  spectra from *Proteus mirabilis* and *Mycoplasma capricolum*. This suggests that the requirement for an iron-storage molecule may be universal.

A similar molecule may also be present as a minor component of a freshwater magnetotactic spirillum in which most of the iron (1.5% of the cell dry weight) is present in chains of magnetite crystals (each about 100 nm across), which account for the alignment of these organisms in the geomagnetic field (Frankel, Blakemore & Wolfe *Science* **203**, 1355; 1979).

It is not yet clear how similar the *E. coli* protein is to that from *Azotobacter vinelandii*, although the chromophore in addition to the non-haem iron also seems to be present in the *E. coli* protein. Fortunately both proteins have been crystallised and the results of further structural studies are eagerly awaited as well as those of biochemical studies which may more clearly establish their biological roles and their resemblance to and differences from ferritin. □

\*Held at Davos, Switzerland on 17–21 April, 1979.

## Errata

In the article 'Acetylcholine receptor clusters' (*News & Views*, **278**, 599; 1979) a line was omitted from the second paragraph, third column, page 599. The sentence beginning on line 12 of that paragraph should read "After the initial stage of cluster formation, the appearance of new hot spots in the absence of a nerve fibre has not been observed on morphologically stable muscle cells."

In the footnote to the article 'Membranes and Parasites' (*News & Views* **277**, 12; 1979) it should be noted that the Special Programme for Research and Training in Tropical Diseases is sponsored by The World Bank, The United Nations Development Programme and the WHO.

## Actinide magnetism: an extraordinary tale

from Gillian Gehring

SOME intriguing experiments on the magnetic properties of actinide intermetallics containing uranium have produced results which cannot be explained by any of the standard theories of magnetism. The most anomalous material is USB (uranium antimonide) which has been extensively studied by Lander *et al.* (Lander *et al. Phys. Rev. B* **14**, 5035; 1976; Lander *et al. Phys. Rev. Lett.* **40**, 523; 1978; Lander *et al. Phys. Rev. Lett.* **42**, 260; 1979) but the behaviour of UN (uranium nitride) which has been studied by Buyers *et al.* (*Proc. Int. Symp. on Neutron Inelastic Scattering*, Vienna, 1978) is similar. However, all the materials  $\text{AnX}$  where An is uranium or neptunium and X is nitrogen, phosphorus, arsenic, antimony, sulphur, selenium or tellurium have the same or similar magnetic phases (Aldred & Lam, *The Actinides: Electronic Structure and Related Properties I* (eds Freeman & Darby) Academic Press, New York, 1974) so that it is possible that what has been seen in USB and UN is actually characteristic of a whole class of compounds and not just due to some freakish property. The properties of a magnetic material depend on a delicate balance between various interactions and it may be that the particular combination characteristic of the actinides; large spin orbit interaction, variable valance and an apparent tendency for metallic f electrons will call for a totally new theory.

Studies of the magnetic properties of materials have been of great importance in helping our detailed understanding of solid state phenomena. This has been, I think, for two main reasons. The magnetic interactions which are odd under time reversal, split electron degeneracies which cannot be removed by any other means so their explanation is a very critical test of our understanding of a material. Also a very wide variety of experiments may be done. Above the phase transition one can measure the susceptibilities of the system to uniform or varying magnetic fields; close to the transition one sees very pronounced fluctuations in the magnetisation which may exist over large regions of space (that is, involving many crystal sites) and decay only slowly with time; at low temperatures one may study the ordered state and measure the magnetic moment per site as a function of

G. A. Gehring is the Physics Tutor at St Hugh's College and a lecturer in the Department of Theoretical Physics in the University of Oxford.

Pauline M. Harrison is a Professor in the Department of Biochemistry at The University of Sheffield.

Fig. 1 The magnetic structure of USb and UN for a domain with  $Q = \frac{2\pi}{a}[001]$

temperature and also measure the magnetic excitation energies.

The AnX crystals have cubic, NaCl structure; in Fig. 1 the magnetic structure for USb and UN is shown. The spins are arranged in sheets perpendicular to one of the crystal axes ( $z$  in Fig. 1) so that all the spins in a given sheet are parallel and adjacent sheets are antiparallel; the magnetic moments are perpendicular to these planes. The moment configuration may be described by

$$m_n = zme^{iQ \cdot R_n} \quad Q = \frac{2\pi}{a}[001]$$

where  $R_n$  is the position vector of the uranium site. In an antiferromagnetic crystal it is very useful to specify the  $Q$  vector which characterises the order. Above the phase transition the  $x$ ,  $y$  and  $z$  directions are all equivalent so there are three possible  $Q$  vectors corresponding to ferromagnetic planes perpendicular to the  $x$ ,  $y$  or  $z$  direction. However, once the planes have been chosen the spins are constrained to lie parallel to  $Q$ . The magnetic moment on the uranium site is  $2.82 \mu_B$  for USb; this is comparable with that of the free ion  $U^{3+}$  ( $J=9/2$ )  $3.42 \mu_B$  or  $U^{4+}$  ( $J=4$ ) of  $3.34 \mu_B$  (Lander *et al. op. cit.* 1976). The magnetic moment distribution on the U sites has been shown to be an oblate spheroid: that is, flattened in the  $z$  direction. The transition temperature of USb is 241.2 K which is considerably higher than that of the equivalent lanthanide compound NdSb for which  $T_N = 13.6$  K.

The high temperature and critical behaviour of USb and UN have been studied by neutron scattering by Lander *et al.* and Buyers *et al.* Since the ordering which is going to occur at low temperatures is characterised by  $Q$  then the system will be expected to show a diverging susceptibility to a magnetic field which has the same alternating spatial dependence, that is

$$h_n = z h_0 e^{iQ \cdot R_n}$$

Such a spatially varying field may be provided by scattering a neutron through wave vector  $Q$ . In such an experiment one looks only at one domain because the scattering done at

or near  $Q = \frac{2\pi}{a}[001]$  for example, will

arise only from those parts of the crystal which are ordering with ferromagnetic planes perpendicular to  $z$ . Above the phase transition the clusters of spins which are ordered are small and they grow as the transition is approached. In both USb and UN the aligned clusters are predominantly in the planes; the correlation length is five times larger in the plane as out of it for USb, for UN it is a factor of three. This is not unusual in layer compounds but USb is cubic so that the neighbouring uranium sites out of the plane are at the same distance as those in the plane. (A very small distortion of less than 0.1% does actually occur at low temperatures.) In addition the direction of the spins is also rigidly fixed perpendicular to the planes so that the system has a negligibly small response to a magnetic field which is perpendicular to  $Q$ . Systems in which the moment may only point up or down are known as Ising systems; they are characterised by a slow relaxation time above  $T_N$ , as is found in USb and UN, and their magnetisation tends to zero at  $T_N$  like  $(T_N - T)^{0.3125}$  (in USb the exponent was found to be  $0.32 \pm 0.02$ ). Again this highly anisotropic behaviour has not been observed before in a cubic compound.

The excitation spectrum at low temperatures is even more anomalous. In ordered magnets the elementary excitations are spin waves. These have been seen in systems, such as  $MnF_2$  or  $NdSb$ , in which the electrons which are responsible for the moment are localised on the magnetic site, and in itinerant ferromagnets such as metallic nickel. The form of the excitation and the way in which its energy depends on wavelength are sketched in Fig. 2 for two extreme models. In the Ising model the angular momentum component in the  $z$  direction on one site has been reduced by one unit. Although this is a localised excitation we may consider a linear combination of these states with wave vector  $k$  but the energy will be independent of  $k$ . This situation arises if the angular momenta are constrained so that only the  $z$  component may be non-zero. The opposite extreme is the Heisenberg model. In

Fig. 2 Sketch of the form of the excitations in Ising and Heisenberg systems with the type of dispersion relation— $w_k$  versus  $k$  plot.

Fig. 3 The dispersion curves for USb; energy plotted against wave-vector transfer  $Q$  (in units of  $2\pi/a$ ). The dashed lines represent the phonon dispersion and are based on the measured open points as well as on our knowledge of phonons in NaCl structures. The magnetic modes are represented by solid squares (the collective excitation) and the hatched area (excitonic level). (From Lander *et al. Phys. Rev. Lett. op. cit.* 1979).

this case all the components of angular momenta may be allowed to be non-zero and an exchange coupling of the form  $\mathcal{J}(\mathbf{r}_{nm})(J_n^x J_m^x + J_n^y J_m^y)$  can transfer the excitation from site  $n$  to  $m$ . The energies of the excitations vary strongly with  $k$ . An intermediate case will arise if there is some anisotropy energy favouring the  $z$  direction and the excitation spectrum will show some dispersion. As the temperature is raised many moment deviations occur; the effect of this is that the energy of the excitations fall (approximately with the magnetisation) and they become less well defined as they scatter off each other. These excitations may be created by a transverse time-dependent magnetic field: this is because the operators which take state  $|J, M_J\rangle$  into  $|J, M_J \pm 1\rangle$  are  $J^x \pm iJ^y$ . At low temperatures a time-dependent magnetic field in the  $z$  direction has very little effect because it cannot create these spin waves. Near to  $T_N$  there is a diffusive response to a time-dependent field  $h_z$ . This behaviour of the transverse and longitudinal excitations has been observed in essentially all ionic and metallic magnets.

The behaviour in USb and UN is quite different. Neither crystal shows

any response to a transverse magnetic field. In USb there is a well-defined excitation for  $T < T_{N/2}$  which has a lot of dispersion as shown in Fig. 3. Its energy increases slightly as the temperature is raised, it is characteristic of a system with equal strengths of interactions between sites in and perpendicular to the planes, and it is excited only by a field in the z direction. In UN there is some evidence of a similar excitation but it becomes very strongly damped away from the point at which it has its minimum energy. Incidentally the minimum energy of this

excitation appears to coincide exactly with the zone boundary energy of the transverse acoustic phonons in both compounds.

There is no way in which the well known theories of localised magnetism nor the theories of itinerant magnetism which work for the transition metal elements and alloys can account for these features. Something really new will be needed in which the interesting but difficult question of localised *versus* itinerant description of electrons will be raised again but this time including spin orbit coupling as a large effect. □

## Bacterial chemotaxis and protein carboxymethylation

from Gerald L. Hazelbauer

MOTILE bacteria migrate along chemical gradients toward higher concentrations of some compounds (attractants) and away from higher concentrations of others (repellents). A number of recent studies of the biochemistry of chemotactic behaviour in *Escherichia coli* and *Salmonella typhimurium* document the central importance of carboxymethylation of a group of membrane proteins. This constitutes significant progress in the understanding of the bacterial sensory response system and is particularly tantalising since protein carboxymethylation has been detected in a large number of mammalian tissues (Kim *et al.* *J. Neurochem.* **24**, 625; 1975; Diliberto & Axelrod *J. Neurochem.* **26**, 1159; 1976) and at least in some cases the reaction appears to be correlated with cellular response to chemical stimuli (Diliberto *et al.* *Proc. natn. Acad. Sci. U.S.A.* **73**, 4050; 1976; O'Dea *et al.* *Nature* **272**, 462; 1978).

An *E. coli* cell swims in straight lines punctuated every few seconds by episodes of uncoordination, called tumbles, that result in new, randomly-chosen directions of swimming. A change in concentration of an active compound over either distance (spatial gradient) or time (temporal gradient) results in an alteration in tumble frequency. Favourable changes suppress tumbles; unfavourable ones induce them. Thus a cell makes net progress along a spatial gradient by longer path lengths in favourable directions. Coordinated swimming occurs when the left-handed helices of bacterial flagella rotate counterclockwise and tumbling occurs when they rotate clockwise. The sensory system in-

fluences migration by controlling the direction of flagellar rotation and the probability of reversals. Sensitivity to active compounds is mediated by specific receptors, some of which have been identified as particular cell surface proteins.

The bacterial response to a gradient is transient. Addition of an attractant to a cell suspension results in an immediate suppression of all tumbles and addition of repellent induces continual tumbling. However after a time ranging from seconds to several minutes, depending on the compound and the magnitude of the gradient, the cells resume their initial behavioural pattern of swimming and tumbling even though the attractant or repellent is still present. Thus bacteria, like many sensory cells in higher organisms, adapt. An important body of work primarily by Goy, Springer and Adler establishes a convincing correlation between adaptation and methylation or demethylation of the methylaccepting chemotaxis proteins (MCPs), polypeptides of approximately 60,000 molecular weight that reside in the bacterial cytoplasmic membrane (see Goy & Springer in *Taxis and Behavior* (Ed. Hazelbauer) Chapman and Hall, 1978 for a summary of that work).

MCPs are methylated by donation of methyl groups from S-adenosylmethionine to form glutamyl 5-methylesters (Kleene *et al.* *J. biol. Chem.* **252**, 3214; 1977; Van Der Werf & Koshland *J. biol. Chem.* **252**, 2793; 1977). The reaction is catalysed by a soluble carboxymethyltransferase apparently specific for MCPs (Springer & Koshland *Proc. natn. Acad. Sci. U.S.A.* **74**, 533; 1977). Mutations in *che* genes generally perturb tactic behaviour. In both *E. coli* and *S. typhimurium* one *che* gene appears to produce the methyl transferase and another a demethylase

(Stock & Koshland *Proc. natn. Acad. Sci. U.S.A.* **75**, 3659; 1978).

Goy *et al.* *Proc. natn. Acad. Sci. U.S.A.* **74**, 4964; 1977) measured the levels of methylation of MCPs during tactic behaviour by *E. coli*. Unstimulated cells exhibit a basal level of methylation. On stimulation the extent of methylation increases (for favourable changes) or decreases (for unfavourable changes), over a period that corresponds to the adaptation time, to a new level which is maintained as long as the chemical environment remains unchanged. The new level of methylation is a function of the magnitude of the stimulus. The straightforward interpretation of these observations is that adaptation is the result of methylation. That predicts that cells unable to methylate MCPs should be unable to adapt. Springer *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **74**, 183; 1977) had previously shown that methionine-starved cells, which should lack the S-adenosylmethionine necessary for methylation, do not adapt but that addition of exogenous methionine subsequent to tactic stimulation allows a delayed adaptation to proceed. Recent studies of *cheX* mutants of *E. coli* by Parkinson and Revello (*Cell* **15**, 1221; 1978) and Goy *et al.* (*Cell* **15**, 1231; 1978) demonstrate that cells in which methylation of MCPs is defective as the result of a mutational block are also defective in adaptation. *CheX* mutants exhibit low levels and aberrant patterns of MCP methylation in both unstimulated and stimulated cells, a phenotype consistent with the *cheX* product being the methyltransferase (Stock & Koshland *op. cit.*). In a constant environment the mutants almost never tumble but temporal gradients of repellents induce tumbling. Using cells induced to tumble, both laboratories showed that temporal gradients of attractants suppress tumbles. The striking defect in the mutants is that they exhibit greatly extended adaptation times. In fact *cheX* cells subjected to relatively strong stimuli maintain the stimulus-induced behaviour of continual tumbling or exclusively smooth swimming for as long as the investigator cares to wait (36 h in some cases). It appears that *cheX* mutations do not significantly affect the ability of cells to be excited by tactic stimuli but only the ability to adapt to them. As the authors suggest it seems likely that the smooth-swimming phenotype of *cheX* strains reflects an inability to adapt to previously encountered stimuli rather than a defect in the tumbling mechanism itself. In any case the observations that two independent blocks on methylation of MCPs result in the same adaptation-defective phenotype provides strong evidence that the reaction is central to

Gerald L. Hazelbauer is at the Wallenberg Laboratory, University of Uppsala.

adaptation.

In addition it is clear that the MCPs are critically important for the transduction of tactic signals from receptors to the flagellar motor. Springer *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **74**, 3312; 1977) and Silverman and Simon (*Proc. natn. Acad. Sci. U.S.A.* 3317; 1977) both demonstrated that two different genes, *tsr* and *tar*, code for MCPs. Mutations in *tsr* eliminate response to one set of stimuli (serine, some other amino acids and some repellents) and those in *tar* to a complementary set (aspartate, maltose and some repellents). Thus excitation mediated by one group of receptors requires the *tsr* function and by another group requires *tar*. The division extends to the methylation reaction. *tsr*-mediated stimuli result primarily in methylation of MCP I, the product of *tsr*, and *tar*-mediated stimuli cause methylation of MCP II. Both sets of authors suggest that MCPs I and II together accept tactic signals from most if not all receptors and thus represent the final stage of signal transduction.

That suggestion may require some revision since Kondoh *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **76**, 260; 1979) describe an MCP III which is methylated upon stimulation by galactose,

ribose or their analogues and is independent of *tsr* and *tar*. This is particularly interesting since the acceptor of signals from galactose and ribose receptors is thought to be the product of the *trg* gene. Mutants in *trg* do not respond to gradients of ribose or galactose but respond normally to other attractants (Ordal & Adler *J. Bact.* **117**, 517; 1974; Hazelbauer & Harayama, *Cell* **16**, 617; 1979). MCP III is not methylated in *trg* mutants but it is not yet clear if the *trg* product is the MCP III protein or instead is a first-stage transducer that funnels into MCP III. In the latter case one might expect to find analogous first-stage transducers for other receptors. The former possibility suggests that MCP I and II should interact directly with the receptors they serve.

It seems evident that much effort will now go into the purification and characterisation of MCPs. The proteins must interact with receptors or first-stage transducers on one hand and with the enzymes of methylation and demethylation and perhaps additional *che* products on the other. An understanding of the mechanisms of signal transduction and adaptation will require a detailed elucidation of those interactions. □

bound-states are seen. Above 3.8 GeV there is a significant increase in the rate of hadron production. Then, as more and more spare energy becomes available, the two quarks have to get faster and jets are formed. Just below 10 GeV the pattern seems to be repeating the narrow 'upsilon' and 'upsilon'' 'bottomonium' states being found (see *News & Views* **273**, 705; 1978). At the new PETRA energies there is just a suggestion of extra hadron production due to  $b$  anti- $b$  production and a slight check in the rate of increase of two-jet properties, though the underlying trend is dominated by the lighter quarks with  $2/3$  charge. The real interest over the next few months will come as energies are increased from 17 to around 30 GeV. Many theorists expect a heavy  $2/3$  charge quark called  $t$  ('top') which should give another clear step in the rate of hadron production along with a sudden dilution of the two-jet structure. When such changes are seen it will be possible to search back in energy to the  $t$  anti- $t$  threshold and then to look for  $\psi$  or 'upsilon'-like 'toponium' states just below it.

One of the collaborations at PETRA, using the PLUTO detector, has reported another important result which especially interested physicists who visited DESY in the first week of April to continue the studies for a very high energy European electron-positron collider (LEP) (see *News & Views* **275**, 482; 1978). The PLUTO group has seen 100 events caused by the collision of pairs of virtual photons, one contributed by the electromagnetic field of an electron in the electron-beam, the other from the field of a positron in the opposed beam. Such events are predicted to be much more frequent at higher beam energies and they may form an unpleasant background to the important single photon annihilation processes. But they also open a new window onto processes which have not yet been studied so their observation at PETRA will encourage those who have been planning special experiments to look at these reactions.

The most important recent result comes, however, not from PETRA but from DORIS. After last year's announcement of their observation of the 'upsilon', the PLUTO group moved the detector to PETRA but continued to analyse data from DORIS. These show that hadron production by way of the 'upsilon' seems to be dominated by three jets rather than two. This has been demonstrated by statistical analyses of particle distribution (see *DESY preprint* 78/71) and they have now reported an 'energy-flow' diagram which shows clear signs of three-jet structure which they claim cannot be

## News from PETRA and DORIS

from David J. Miller

THE new electron-positron storage-ring PETRA has now been working for about 6 months at the DESY laboratory near Hamburg and the first physics results have just been reported. They are interesting but not unexpected. Three detectors were used, each manned by a different international collaboration of universities and national laboratories. All see the same sorts of effects, but with different sensitivities (see for example *DESY preprint* 79/11 and papers in recent issues of *Phys. Lett.*). Data have been collected at total energies of 13 GeV and 17 GeV. There is evidence for the increase, as energy is increased, of the tendency for strongly-interacting particles (hadrons) to be produced in a pair of 'jets'. A jet is a cluster of particles all moving in roughly the same direction and all generated, according to present theories such as quantum-chromodynamics (QCD) (see *News & Views* **277**, 349; 1979) by one fundamental parent—a quark or a gluon. In QCD the underlying interaction is supposed to be between quarks and gluons; the quarks behaving like particles when within a femtometre of each other but needing to convert

themselves into pions and other genuinely free hadrons when they try to separate. Fast gluons are expected to form jets in a similar way. As well as their clear two-jet structure, the PETRA data on the interaction rate and on the number of particles produced conform to the pattern which has been observed at lower energies with the SPEAR storage-ring in California and up to 10 GeV with the DORIS rings at DESY.

All hadron production by electron-positron annihilation can still be explained by production of pairs of quarks and antiquarks from the set  $u$ ,  $d$  (the quarks in normal matter such as protons or neutrons),  $s$  (the strange quark),  $c$  (the charmed quark) and  $b$  (the heavy 'bottom' quark). Since the production process goes by way of a single intermediate photon the contribution due to each type of quark depends on the square of its electromagnetic coupling—that is, the square of its charge. The bottom quark appears to have  $1/3$  times the electron charge so it is produced at only one quarter of the rate at which the  $2/3$ -charge  $c$  quark is produced. The threshold energy for  $c$  anti- $c$  production is about 3.8 GeV. Below that the narrow  $\psi$ -J and  $\psi'$  'charmonium'

David J. Miller is in the Department of Physics, University College, London.

reproduced by any other simple mechanism. Some theorists are hailing this result as the proof that gluons exist, though many people are not fully convinced.

If the  $\psi$  is produced by way of a single photon then it must have negative charge-conjugation parity (C-parity). Since the  $\psi$  is too light to decay to the  $b\bar{b}$  continuum it can only decay to quarks if the weak interaction turns a  $b$  into a lighter  $c$  quark, but that is a very slow process. In the meantime there is predicted to be a high probability that it can decay into gluons. But gluons are like photons in a number of ways. In particular, they also should have negative C-parity, so the  $\psi$  can only conserve C-parity if it decays to an odd number of gluons. Energy-momentum conservation forbids decay to one gluon and the phase-space probability is small for five gluons or more. Sceptics claim, correctly, that other three-jet models can be constructed, but QCD does predict that three gluon jets should be seen and the PLUTO results must therefore be taken seriously as at least circumstantial evidence for the existence of gluons inside hadrons.  $\square$

## Ten years after . . . a decade of lunar science

from C. T. Pillinger

THE 10th anniversary meeting of the Lunar and Planetary Science Conference\* met under the shadow of recent budgetary constraints imposed by the US Congress. The growing 'planetary' nature of the conference was marked; indeed discussion on new data from lunar soils has diminished substantially from its originally dominant position. Data from new planetary missions, meteorites and studies of fundamental processes on the Moon attract more interest from today's planetologist.

A highlight of the conference was the presentation of new results from the Viking, Voyager and Pioneer missions. A short 3-D film of Mars, created from elegant computer techniques by E. Levinthal (Stanford University), preceded spectacular close-up pictures of Jupiter and the Gallilean satellites, providing exciting new venues for geological speculation. The volcanic activity on Io, and apparent tectonic effects on Ganymede, will no doubt provide the basis for much discussion at future meetings. The composition of the atmosphere of Venus, with its apparently 'solar' rare gas

abundance (see *News & Views* 278, 777; 1979), leads one to speculate as to how radically our current ideas of planetary formation may have to be revised over the next 10 years.

As pointed out by S. R. Taylor (Australian National University, Canberra), 10 years study of the Apollo samples has failed to achieve consensus on the origin of the Moon, although considerable constraints can be inferred. Existing disagreements continued over the criteria for estimating siderophile element abundances indigenous to the highland crust and the whole Moon. Delano and Ringwood (Canberra) disputed the elemental correlations calculated by the group of E. Anders (University of Chicago). The importance of the argument is the validity of the assertion by Ringwood that the Moon was derived from the Earth's mantle after formation of the Earth's core, as opposed to condensation as a discrete body. A third position was adopted by Wanke *et al.* (University of Mainz) who, on the evidence of Co/(Fe + Mg) ratios, favoured a genetic relationship between the Earth and Moon.

Continued studies of lunar drill core samples have clarified ideas concerning reworking and deposition processes in the lunar surface layer, known in lunar parlance as 'the regolith'. Soil exposure indices have been based on a number of irradiation effects and petrographic particle size data. However, the relative importance of erosion compared with deposition processes (for example sputtering, impact volatilisation and deposition, and micrometeorite erosion) continues to be the subject of lively debate.

Wieler *et al.* (University of Zurich) showed that 0.5 billion year old soils had similar solar rare gas ratios to the present; no information on the solar wind flux in the past was forthcoming, although various workers have postulated an increased flux of varying isotopic composition in earlier irradiation. The magnitudes of the postulated changes seem to be at variance with existing models of solar processes.

Meteoritic studies have benefited from techniques developed for the lunar programme, and the growth of such investigations was evident. The Allende meteorite in particular has been subjected to intensive study. The Caltech group presented a detailed study of a new hibonite-rich inclusion (HAL); hibonite is considered to be one of the highest temperature major element condensates from the solar nebula. This inclusion consisted of an unusually pure hibonite core and several rims of lower-temperature

phases. Comparison with other Allende Ca, Al-rich inclusions implied a large  $^{26}\text{Mg}$  anomaly; however, this was not found, suggesting a low  $^{26}\text{Al}$  content for HAL. Ca isotope shifts in all phases were found to be large but uniform, and small nonlinear effects attributed to a nuclear origin. HAL thus qualifies as a new Allende isotopically-anomalous inclusion. Jessberger *et al.* (University of Heidelberg) reported a very high  $^{39}\text{Ar}/^{40}\text{Ar}$  apparent age of over 5 billion years, which can either be interpreted as a very old component, or a possible  $^{40}\text{K}$  isotopic enhancement. The latter possibility should be resolved by work now under way in Mainz. The existence of very old inclusions ( $> 5$  billion years) would imply that either these inclusions originated from outside the condensing solar nebula, or that the currently accepted age of the Solar System of 4.5 billion years needs to be re-assessed.

Strongly nonlinear kinetic isotope fractionations of the three stable isotopes of oxygen have been produced in the laboratory. G. Arrhenius (La Jolla) suggested this effect as another source of the nonlinear isotopic behaviour, to complement the nucleosynthetic processes. The latter were proposed to explain the original discovery of such anomalies in oxygen by R. N. Clayton in 1973.

Recent and previous discoveries of isotopic anomalies place constraints on possible models of the origin of the Solar System. However, considerable latitude is still available, as a number of apparently contradictory models were discussed at length mainly by D. D. Clayton (Rice University) and A. Cameron (Harvard University).

An interesting new sample collection method, which may be important to future research, is the 'cosmic muckrake' of Brownlee and others. Using a magnetic rake dragged across the ocean floor, large quantities of extraterrestrial material can be recovered. In a typical day's operation, the device processed  $\sim 10^7$  kg of sediment, and separated about half a million particles, many of which were identified as extraterrestrial. Debris from nearly every type of object which has collided with Earth over the past  $10^9$  years might be collected.

The few contributions mentioned outline some promising research emerging in planetary science. The emphasis on the Moon a decade ago has given new impetus to the older science of meteoritics; additionally, new information from hitherto inaccessible objects is now becoming available.  $\square$

## Games parasites play: how parasites evade immune surveillance

Barry R. Bloom

Albert Einstein College of Medicine, Bronx, New York 10461

*Parasites have evolved an extraordinary variety of mechanisms for surviving in the face of the natural and acquired immune responses of their hosts. A selection of the mechanisms serves to illustrate the challenge involved in developing strategies for immunising against parasites.*

THE games parasites play are, in fact, a serious matter (see refs 1–11 for reviews). It is estimated that between 500 million and 1,000 million people, primarily in the developing countries, suffer from tropical diseases and parasitic infections. Table 1 indicates current estimates on the prevalence of some parasitic diseases. In addition to the diseases of man, millions of cattle die of parasitic diseases each year (Table 2) and at least 700 million are estimated to be at risk. In Africa alone, 7 million square kilometres of grazable land capable of supporting 120 million head of cattle remain largely unproductive chiefly because of two parasitic diseases—trypanosomiasis and East Coast fever.

There is currently a resurgence of interest in tropical diseases, and in the possibility of providing immunological protection against many of them. The challenge to the immunologist, in trying to engender resistance or immunity to these parasites, is to improve the natural capability of the host's immune system, given that the survival of parasites and the extent of their ability to live in the host species reflect the fact that they have evolved mechanisms for surviving in the face of the best the body has to offer in the way of natural and acquired immunity.

In the simplest of terms, the general ground rules of the game may be sketched as follows: If parasites totally eluded the immune response and were sufficiently virulent, they would kill their hosts on whom their survival depends and preclude their own survival. Conversely, if they were too easily destroyed by the immune response, their survival would be similarly jeopardised. Consequently, immunity and escape from surveillance are relative phenomena which exist in balance and tension.

My intention here is to outline some of the mechanisms currently put forward to explain escape from surveillance. From this rapidly accumulating knowledge there should arise some new approaches to the prevention of parasitic diseases. It is to be expected that as these approaches are applied, they will be recognised by the parasites as selective pressures to be overcome, and they will devise even more sophisticated mechanisms for eluding the host's immune response. But one may hope that the time frame of evolution will be a great deal longer than the time frame required to bring most infectious diseases under some control.

### Old-time genetic engineering

In West Africa, there is considerable variability in susceptibility among various breeds of cattle to infections produced by *Trypanosoma congolense*. Cattle introduced to Africa from Europe during the time of the Roman Empire as well as native zebu cattle are highly susceptible to this parasite. Indigenous West

African short-horned cattle such as the n'dama and muturu seem to be naturally much more resistant<sup>12</sup>. This is an example of what is generally termed 'natural immunity'. The spectrum of natural immunity is illustrated by the fact that there can be some parasites such as *Trypanosoma b. brucei* and *Trypanosoma cruzi* within a single classification which have enormous host ranges and are capable of infecting and growing in virtually all domestic mammals; others, such as *T. simiae*, can produce fulminating infection in only a few, apparently unrelated, species such as monkeys and pigs; and there may be others which produce infections with more limited host range, such as the exclusive infection of cattle by *Theileria parva* or certain species of monkeys by the monkey malaria agent, *Plasmodium knowlesi*. The mechanisms underlying these host restrictions remain largely unknown; yet were such mechanisms understood, it might be possible to learn much about the parameters which govern host-parasite interactions.

In spite of the current enthusiasm about immune response (Ir) genes, in a wide variety of experimental bacterial, viral and parasitic infections studies in inbred mouse strains, it has not yet been established that natural host resistance is primarily dependent on genes associated with the major histocompatibility complex. Within a host species, however, there may be striking genetic differences in susceptibility to parasitic infection. This is perhaps best illustrated by studies on two protozoa that cause quite different diseases in man—*Leishmania donovani*, the causative agent of visceral leishmaniasis or kala-azar and *Trypanosoma cruzi*, which produces Chagas' disease in Latin America. When various inbred mouse strains were studied for susceptibility to *L. donovani* by Bradley<sup>13</sup>, C3H/He mice seemed to be most resistant and C57B1/6, most susceptible. By appropriate crosses it was possible to show that there was a single major autosomal dominant gene which controlled resistance, and that this gene was not H-2-linked. Studies in our

Table 1 Some parasitic diseases in man

	Estimated prevalence
Hookworm	700,000,000
Trachoma	400,000,000
Schistosomiasis	200,000,000
Malaria	150,000,000

Chagas' disease	12,000,000
Sleeping sickness	Unknown
Leishmaniasis	Unknown

R504 R 405

laboratory on resistance to *T. cruzi* in the same strains of mice, revealed an almost reciprocal pattern of susceptibility<sup>14</sup>. Here the C3H is susceptible and the C57B1, relatively resistant. Again we have found resistance to be unlinked to H-2. It is obviously of great interest to pursue the mechanisms by which these major autosomal genes control resistance. In Bradley's studies, there was some evidence that an H-2-linked gene exerted a secondary influence on resistance following infection. In this regard studies of patterns of the major human histocompatibility complex (HLA) antigens in Sardinia by Piazza *et al.*<sup>15</sup> showed significant differences in the HLA-B locus antigens between inhabitants of the highlands, an area in which malaria was essentially non-existent, and of the lowlands, an area in which malaria flourished until recently. This suggests that there may have been a selection for certain HLA-B-linked, possible Ir gene functions by the malarial parasite.

The converse situation, in which the outcome of infection is modified by the genetics of the parasite, is illustrated by three extraordinarily different disease entities of man in three different parts of the world caused by *Leishmania*, a genus of protozoan parasites which grows exclusively in macrophages in man and certain animal reservoir hosts. *Leishmania donovani* causes the systemic, progressive non-healing disease, visceral leishmaniasis, known in South Asia as kala-azar; *Leishmania tropica* causes Oriental sore found mostly in the Middle East and which is a local, cutaneous, self-healing lesion; and *Leishmania brasiliensis*, which causes mucocutaneous leishmaniasis in Central and South America with its most fulminating form known as espundia, a disease in which the parasite destroys the soft tissue and literally makes its victims faceless. Our lack of knowledge about the genetic control of pathogenesis makes it impossible to understand how three such different diseases can be produced by related organisms that grow in the same cell type. Nor why the same organisms inhabiting different host species produce different patterns of disease than in man.

### How parasites change their spots: antigenic variation

There is no more striking example of successful adaptation of a parasite to the host's immune response than that exhibited by African trypanosomes, which live entirely extracellularly, particularly in the blood stream and lymph of ungulates or man where they cause sleeping sickness. As long ago as 1907 Massaglia (see ref. 16) observed that following infection through the bite of the tsetse fly, the numbers of parasites in the blood fluctuated periodically. He suggested that this succession of parasitaemia, remission and recrudescence was due to the destruction of trypanosomes by host antibody and the emergence of parasites of different antigenic constitution. The course of these waves of parasitaemia in a single patient described in 1910 is illustrated in Fig. 1. Human sleeping sickness is caused primarily by two subspecies of *Trypanosoma brucei*, namely *gambiense* and *rhodesiense*. Each wave of parasitaemia is followed by the production of antibodies, generally agglutinins or lysins, which are specific for an individual variant, that is the antigen type of the previous wave of parasitaemia. Antigenic variation has also been described in the genus *Plasmodium*, which causes malaria, and in *Babesia*, tick-borne parasites causing a malaria-like disease.

What are the possible genetic and regulatory mechanisms which could explain antigenic variation? The simplest hypothesis would be that most infections contain a mixed population of parasites comprising several strains, and as the predominant

strain grows and is killed, there is simply outgrowth of another variant type present in the original inoculum. This hypothesis was essentially disproved by experiments in which single trypanosomes were cloned and maintained in immunologically compromised animals and antigenic variation was not seen. When transferred to conventional animals, even though the entire population was derived clonally from a single organism, antigenic variation emerged<sup>17</sup>.

A second hypothesis invokes mutation, possibly involving expression of small determinants in the molecule which are immunodominant and which could vary randomly to elude the immune response. A mutation frequency of  $1.2 \times 10^{-5}$  would explain the appearance of variants in a clone at 3–4 day intervals. But Gray showed that antigens of a clone tend to appear in an apparently programmed sequence<sup>18</sup>. Thus, display of variant antigens A-B-C-D-? appears to be non-random, and passage of variants at any stage back through the tsetse fly results in reversion to the basic antigenic variant types of the strain. It is difficult to explain a programmed sequence on the basis of simple random mutation.

The mechanism believed to be most relevant to African trypanosomes is adaptive phenotypic variation, in which the parasite has a finite number of genes which can code for its surface antigens and which it can switch on and off in regular sequence. As gene activation and translocation is one of the central problems in molecular biology, the African trypanosomes provide an extraordinarily interesting model for study.

Fig. 1 Parasitaemia occurring in a patient with African trypanosomiasis. From Vickerman<sup>16</sup>.

What is the nature of the antigens that vary? Cross<sup>19,20</sup> has demonstrated that the outer surface of *Trypanosoma b. brucei* contains a coat or glycocalyx that is composed principally, if not exclusively, of the variant-specific glycoprotein antigen. This antigen has a MW of 67,000, and constitutes 10% of the entire cell protein and 30% of the soluble proteins. The variant glycoprotein molecules contain between 7 and 17% carbohydrate attached to the portion of the molecule associated with the plasma membrane. About  $7 \times 10^6$  molecules are found per trypanosome, a number probably sufficient to cover the entire surface of the parasite, and it is possible that this coat, which projects 12–15 nm from the plasma membrane, may serve as a spacer or barrier sufficient to prevent antibody to common membrane antigens from ever reaching the plasma membrane and lysing the organism. Amino acid sequencing of the N-terminal ends of four isolated purified variant glycoproteins revealed essentially no structural homologies. Each had a unique sequence, and there was no obvious evidence for deletions or frameshifts, thereby apparently eliminating the simple mutational hypothesis for antigenic variation.

Does antibody select or induce the antigenic variants? As early as 1909 Ehrlich found that trypanosomes incubated with homologous antiserum and then injected into mice produced a parasitaemia of a different variant type. As mentioned before, passage of clones of trypanosomes or variants in immunologic-

Table 2 Some parasitic disease of cattle

	Estimated annual mortality
African trypanosomiasis	3,000,000
Anaplasmosis	1,000,000
East Coast fever	500,000
Babesiosis	250,000

ally incompetent animals results in clonal fidelity. Gray<sup>21</sup> was able to perturb the programmed antigenic succession in the rabbit by passively protecting animals against four variants of a strain and then challenging with that strain. The rabbits then produced antibody to a fifth variant when challenged with the original strain.

It has become possible for the first time to cultivate the bloodstream form of the African trypanosomes *in vitro*<sup>22</sup> using a bovine cell feeder layer, and it is now possible to analyse *in vitro* molecular mechanisms of genetic and regulatory control underlying antigenic variation. Doyle *et al.*<sup>23</sup> followed 19 clones of a variable antigen type of *T. b. brucei* *in vitro*, and, in the absence of antibody, observed new variants arising spontaneously in nine clones, with a frequency of approximately  $10^{-3}$ – $10^{-4}$ . In the absence of immunoselection *in vitro*, the ability to detect variant types was related to their ability to outgrow the initial population, suggesting that two mechanisms of selection for variants are likely to be operative *in vivo*, altered growth rates and immunoselection. It remains to be established whether antigenic variants from a clone occur randomly or not, and whether antibodies affect the variation frequency or merely select for spontaneously occurring variants. Nevertheless, the high frequency of spontaneous variants observed in these *in vitro* studies can be considered to support mutational hypotheses for antigenic variation, as the accumulation of large numbers of mutations in the genes coding for surface antigen could lead to production of variants of markedly differing surface antigenicity and amino acid sequences.

As another possible mechanism of antigen modulation it is important to consider the possibility that parasites can 'cap' and shed their surface antigens to elude the immune response. Doyle *et al.*<sup>24</sup> have shown that within minutes after exposure of leishmania to fluorescent antibodies at 37 °C, the parasites shed their surface antigens and become refractory to the effects of immune sera and complement. It is not known whether capping occurs *in vivo* and represents a significant mechanism for escape of protozoa from immune attack.

### Antigenic mimicry and concomitant immunity

While the term 'concomitant immunity' is most familiar in the context of a tumour-bearing animal in which an autochthonous transplant of the primary tumour is rejected while the primary tumour grows progressively to kill the animal, there is a precisely analogous phenomenon which occurs during infection with a number of parasites. Concomitant immunity<sup>25</sup> is a form of acquired immunity in which the established parasitic infection persists long after resistance has developed against a challenge infection. In contrast, 'premunition' is used to describe the situation in which infection is suppressed although not eliminated by the host<sup>26</sup>.

Concomitant immunity is well documented in schistosomiasis, a chronic disease caused by the trematode genus *Schistosoma*. *S. mansoni* and *S. japonicum* reside in the portal and mesenteric systems and produce a hepatosplenic disease. *S. haematobium* causes a disease of the urinary tract. Adult schistosome worms can reside in the mesenteric venules for many years with little evidence to indicate that they stimulate any immune response at all. However, if adult schistosome worms are transferred to portal veins of monkeys which have never experienced the immature migrating forms, the monkeys become capable of resisting infection when challenged with the immature larval form (cercaria) even though they could not reject the transferred adults<sup>27</sup>.

How can this type of concomitant immunity be explained? One possibility is that the parasite, by natural selection, has evolved some antigenic determinants similar or identical to those of the host. One difficulty with this hypothesis, at least with respect to schistosomes, is that the organism can live in a variety of mammalian hosts, and it is unlikely that an organism would have evolved major antigens common to all hosts. An alternative hypothesis, originally suggested by Smithers and Terry<sup>25</sup> is that schistosomes adapt to the range of hosts in which they live

by appropriating some host molecules onto their surface layer or tegument. This has been amply demonstrated for *S. mansoni*<sup>27</sup>. Worms grown in both mice and gerbils were transferred either to normal rhesus monkeys or to monkeys immunised against the erythrocytes of mice or gerbils. The adult worms transferred to normal monkeys resumed their egg laying and were viable after about 5–6 weeks. Adult worms transferred from mice to monkeys immunised against mouse erythrocytes failed to establish themselves and were killed. But monkeys immunised against mouse erythrocytes failed to inhibit the growth of adult worms grown in gerbils. These experiments suggested that the worms grown in mice had acquired mouse antigens on their surface.

In order to explain concomitant immunity, it is necessary to argue that the host antigens are acquired by the adult worms but are not found on the immature forms, as the immune response of the chronically infected host can kill the immature forms. Clegg *et al.*<sup>28</sup> demonstrated that the most immature form, the cercaria, is not killed by the monkeys immunised against mouse erythrocytes, and hence does not appear to have host antigens, but that by 7 d the intermediate stage of the parasite, the schistosomulum, has already acquired host antigens.

What are the host antigens acquired by these organisms? Schistosomula cultured with human type A, type B or type O erythrocytes have been shown to acquire A, B and H blood group antigens respectively on their outer layer<sup>29</sup>. Blood group Rh or MN determinants are not found on the schistosomula but several other host serum proteins have been found. Most exciting is the recent evidence of Sher *et al.*<sup>30</sup> that schistosomula can acquire mouse histocompatibility antigens, the major determinants of immunological recognition of 'self', and this offers an exquisite mechanism for mimicry of 'self'. Intriguing as these data are, there is as yet no conclusive evidence establishing that 'mimicry' is the mechanism primarily responsible for the failure of adult worms to be rejected by the host.

### Learning to live in macrophages

From the time of Metchnikoff, macrophages have been described as highly phagocytic scavenger cells capable of killing and degrading a wide variety of microbes. Nevertheless a number of microorganisms including *Mycobacterium tuberculosis*, *Mycobacterium leprae*, and protozoa of such genera as *Toxoplasma*, *Besnoitia*, *Leishmania* and *Trypanosoma cruzi* survive and grow inside macrophages for part, or all, of their stay in the mammalian host.

Extracellular particles which are phagocytised by macrophages enter by invagination of the plasma membrane and appear in phagocytic vesicles<sup>31</sup>. There follows a fusion between the phagocytic vesicle and primary lysosomes, known to contain degradative enzymes, and probably peroxisomes as well, to form secondary lysosomes. In addition, fusion between secondary lysosomes and phagocytic vesicles is also known to occur. At least three different mechanisms can be defined from studies *in vitro* to account for the ability of parasites to evade killing by the macrophage, although the molecular basis for these phenomena and their relevance to the survival of parasites *in vivo* remain unclear.

(1) Failure to fuse: A number of parasites have evolved mechanisms to prevent fusion of macrophage lysosomes with the phagocytic vesicle containing the invader. Human virulent tuberculosis grows in vesicles within macrophages, but these fail to fuse with lysosomes<sup>32</sup>. Fusion can be induced by opsonisation (coating viable mycobacteria with antibody) but the organism retains its viability<sup>33</sup>.

A very similar pattern has been recorded for *Toxoplasma gondii*<sup>34</sup>. Once again, viable organisms were readily ingested by macrophages *in vitro*, but there was a failure of lysosomes, for example secondary lysosomes labelled with Thorotrast, to fuse with the phagocytic vesicle. Opsonisation of the parasite with antibody permitted fusion of secondary lysosomes with the phagocytic vesicle. In this case, the effect of antibody is to facilitate killing of the *Toxoplasma*. The mechanisms by which

the living parasites are able to block lysosomal fusion in host cells remain largely unknown.

(2) Resistance to killing: As mentioned above, when *M. tuberculosis* is opsonised, lysosomal fusion occurs, but the mycobacteria are perfectly capable of surviving within the lysosome. *M. lepramurium* also grows in vesicles which fuse avidly with primary and secondary lysosomes even without opsonisation<sup>32</sup>. Similarly, leishmania grow exclusively in macrophages, and survive and multiply in lysosomes even after fusion has occurred<sup>35</sup>.

A subtle example of survival in macrophage lysosomes is provided by two species of *Leishmania*. *L. enrietti* produces a disease similar to human cutaneous leishmaniasis or Oriental sore in the guinea pig; *L. tropica* produces a similar disease in some strains of mice. When macrophages from mice sensitised to *L. enrietti* were activated and then challenged *in vitro*, Mauel and Behin<sup>36</sup> found them to be resistant to *L. enrietti*. However, when similar procedures were used for activating guinea pig macrophages, *L. enrietti* was not killed. In contrast, activated guinea pig macrophages were highly resistant to *L. tropica*, but failed to resist challenge with *L. enrietti*. Thus, these leishmanias have developed quite specific, but unknown, mechanisms for eluding the destructive capability of macrophages from the species which they normally infect, while being susceptible to the killing mechanisms of activated macrophages from animal species which are resistant to infection by them. An elegant control in these experiments was the simultaneous infection of activated guinea pig macrophages with *L. enrietti* and *Listeria monocytogenes*, to ascertain whether the leishmanias survived by nonspecifically blocking the macrophage cytotoxic mechanisms<sup>37</sup>. The results obtained were surprising in that, in the same phagosomes, listeria were killed but the leishmanias survived. Thus, there is an extraordinary selectivity in the evolution of resistance to macrophage killing by *Leishmania*.

(3) Escape from the lysosomes: In studies on the interaction of *Trypanosoma cruzi* with normal and activated murine macrophages<sup>38-40</sup> it was observed that within 2 h virtually all trypanosomes were in phagocytic vesicles, and that lysosomal fusion almost invariably occurred (Fig. 2b). Resident unstimulated peritoneal macrophages were as effective as BCG-activated macrophages in killing and degrading a high proportion of the infecting organisms within the first 24 h. However, when infected cultures were examined at 72-96 h, a remarkable picture was seen. Resident macrophages were found to have large numbers of trypanosomes growing within the cytoplasm, and when the Thorotrast labelling technique was used, virtually none of these parasites could be found in a vesicle containing the lysosomal marker (Fig. 2c). They appeared to be able to escape from their precarious state within the lysosome, and take up residence in the cytoplasm, where the macrophage has no specialised mechanism for killing foreign invaders. In contrast, by 3-4 d after infection, macrophages nonspecifically activated by BCG had essentially killed and degraded virtually all of the parasites; only debris was seen (Fig. 2d). Recently, Noguiera and Cohn<sup>41</sup> have been able to activate resident mouse macrophages *in vitro* to kill *T. cruzi* using products of activated lymphocytes.

### Jamming the immune response

One of the intuitively obvious adaptive mechanisms by which parasites could elude the normal host response would be by suppressing the immune response itself. Several organisms are known to use this method. For example, immunosuppression has been reported in hamsters infected with *Leishmania donovani*<sup>42</sup>, mice infected with *Toxoplasma gondii*<sup>43</sup> and rats infected with roundworm, *Nippostrongylus brasiliensis*<sup>44</sup>. However, by far the most impressive and clinically important instances of the immune suppression of the host response occur in African trypanosomiasis<sup>45-47</sup>, malaria<sup>48</sup> and kala-azar. In human sleeping sickness and malaria, elevated levels of IgM are characteristic, on occasion rising to 5 g per 100 ml<sup>49</sup>. In spite of extraordinarily high levels of IgM, 5% or less of these immuno-

**Fig. 2** a, Normal mouse peritoneal macrophages infected with epimastigotes of *T. cruzi* at a ratio of 1:1 after 2 h. Note that parasites are in the process of being digested (arrow).  $\times 2,500$ . b, BCG-activated macrophage infected with *T. cruzi* at a ratio of 10:1 after 2 h. Thorium dioxide is seen in secondary lysosomes and fusion with parasite-containing vacuole (arrow).  $\times 2,500$ . c, Normal mouse peritoneal macrophage at a 1:1 infection ratio after 96 h. Trypanosomes are present in cytoplasm where division has begun to occur (arrow). There is no evidence of lysosomal fusion.  $\times 4,000$ . d, BCG-activated mouse peritoneal macrophage after 192 h of infection with *T. cruzi*. There is no evidence of trypanosomes and some evidence of secondary lysosomes.  $\times 2,000$ .

globulins have been found to react specifically with antigens of *Plasmodium falciparum* or *Trypanosoma gambiense*, the parasites responsible for malaria and sleeping sickness in West Africa<sup>49</sup>. In both diseases the responses of patients to salmonella antigens and tetanus toxoid, and animals to sheep erythrocytes (SRBC), are markedly reduced<sup>46</sup>. In this paradoxical situation there is a heightened production of antibodies to the parasites with depressed humoral immunity to other antigens.

Several animal models have been developed to probe the mechanisms of this type of immunosuppression. For example, mice infected acutely or chronically with *Plasmodium berghei* malaria show a marked depression in development of antibody producing cells to SRBC in the Jerne plaque assay, the effect being more pronounced on the IgG plaques<sup>48</sup>. Even more striking suppression is seen in mice infected with *Trypanosoma b. brucei*<sup>47</sup>. Perhaps even more impressive than the suppression of antibody production is the marked increase in the background of antibody plaque forming cells to SRBC, generally at least a log higher in infected than in uninfected animals. Thus, infection with plasmodia or trypanosomes causes a marked increase in the background antibody forming cells not only to SRBC but also to donkey, horse or TNP-coupled SRBC. The high background and lack of specificity are strongly reminiscent of the observations made on mouse spleens treated 1-2 d before immunisation with a polyclonal mitogen, such as endotoxin

(lipopolysaccharide, LPS)<sup>50</sup>. There is an increase in immunoglobulin, an increase in polyclonal antibodies which account for the background, and a diminution in specific plaque-forming cells. These experiments suggest that one mechanism for inducing immunosuppression is a polyclonal mitogenic activity of the malaria and trypanosome parasites<sup>47</sup> causing many clones of B lymphocytes to undergo division and differentiation. Clearly other mechanisms, such as suppression by T cells, may be operative as well<sup>51</sup>.

Observations on the immunosuppression by parasites have implications beyond the survival of the specific parasite. It is well known that patients with sleeping sickness have an increased susceptibility to secondary bacterial infections, a problem recognised in some of the earliest studies on the disease. Children in the tropics with acute falciparum malaria also have high rates of bacterial infection; although it must be noted that many also have other parasitic infections, and frequently, protein calorie malnutrition and avitaminosis as well. Nevertheless, antibody responses in children to tetanus toxoid from villages where malaria prophylaxis is carried out are higher than those from comparable villages where malaria infection is frequent<sup>46</sup>. Furthermore it may not be coincidental that Burkitt's lymphoma<sup>52</sup> occurs mainly in geographical areas coincident with holoendemic malaria. It is not inconceivable that the malaria-induced immunosuppression could provide a favourable environment for development of lymphoma viruses. This possibility has received some experimental confirmation from the studies of Wedderburn in mice in which the incidence of lymphomas in mice infected with both malaria and murine leukaemia virus was dramatically higher than those receiving the virus alone<sup>53</sup>.

### Subversion of the immune system

While the above examples illustrate the ability of parasites to evade the immune system, there are at least two fascinating examples in which the immune system may be requisite for survival of the parasite. *Babesia* and *Theileria* species are protozoan blood parasites transmitted by ticks that can infect mammalian hosts. *Babesia* produces a malaria-like disease in cattle all over the world and *Theileria parva* causes a disease known as East Coast fever which affects cattle primarily in East Africa. *Babesia* Spp. occasionally produce disease in humans.

It has recently been found that *Babesia* seems to require complement activation in order to penetrate the erythrocyte in which it grows. C3 or C5 deficient mice or mice treated with cobra venom are protected from infection<sup>54</sup>.

Unquestionably, the most fascinating case of subversion of the immune system is that of *Theileria* species. These parasites enter lymphocytes and transform them into proliferating lymphoblastoid cells<sup>55,56</sup>. The intracellular parasite, in its large form called the macroschizont, divides by binary fission, and increases in number 10-fold every 3 d until almost all the lymphoid cells are parasitised<sup>57</sup>. During this process there is a marked lymphocytosis resembling the uncontrolled growth of a leukaemia or lymphoma. From about the tenth day of infection, increasing numbers of the macroschizonts break apart into a large number of microschizonts. In the process, host lymphocytes are destroyed and small infectious particles termed micromerozoites are released and invade red cells. There the parasite develops an intra-erythrocytic stage, after which there is a depletion of leukocytes and haematopoietic cells leading to death. In enzootic areas in East Africa, 40% of the calf crop may die from East Coast fever.

The most extraordinary aspect is that when lymphoblasts obtained from cattle infected with *Theileria* are put into tissue culture, they develop into continuously growing lymphoblastoid cell lines with clonal replication of both parasites and cells<sup>58</sup>. Sporozoites from the tick will transform normal bovine lymphocytes *in vitro*, thus *Theileria* species seem to be the only parasite other than oncogenic viruses capable of transforming lymphocytes into continuous growth.

Sceptics may argue that it is unlikely for a protozoan to induce neoplastic transformation of lymphoid cells, and that the parasite may be carrying an oncogenic virus. Yet it has recently been possible to cure the lymphoblastoid cells of the parasite using drugs<sup>59,60</sup> and they revert to small lymphocytes and stop growing. In any case, the continuous, persistently infected bovine lymphoblastoid cell lines, when transferred back to susceptible cattle, can engender protection to infection with *Theileria parva* or *Theileria annulata* in more than 80% of the instances<sup>61,62</sup>, and offer the possibility of a vaccine.

### Commentary

Several important new programmes in research in parasitic diseases have been initiated since 1976, prompted by increased awareness of the urgent health needs of developing countries and a commitment that basic biomedical research can provide new means for intervening in at least some of these diseases. Among these initiatives are the UNDP/World Bank/WHO Special Programme for Research and Training in Tropical Diseases, the Great Neglected Diseases Program of the Rockefeller Foundation and the establishment of the International Laboratory for Research in Animal Diseases in Nairobi.

Is there any reason to believe, in light of the subtle and sophisticated ways by which parasites elude immunological attack, that immunological approaches offer any promise? The tremendous advances in understanding basic cellular and humoral immune responses in model systems provide a basis for analysis of the mechanisms of natural and acquired resistance to parasites. The recent development of techniques to produce monoclonal antibodies by means of B-cell-myeloma hybrids (hybridomas) offers the possibility of identifying antigenic determinants, even minor ones, required for engendering resistance to infectious agents. Even if such protective antigens cannot be obtained in large amounts by cultivation of the parasites, as is the case for the blood form of the malaria parasite infectious for red cells or the common, non-varying metacyclic antigen found only on the insect form of the African trypanosomes, the monoclonal antibodies, together with recombinant DNA technology, could be useful for selecting clones of transformed *Escherichia coli* or yeast expressing the protective antigens of parasites which could be used in vaccines. Finally, the recent developments in soluble and liposome adjuvants offer increased possibilities for safe and effective enhancement of immune responses in man.

As in other areas in which basic scientific approaches are applied to disease-related problems, the study of immunity to parasites may provide a new and fundamental knowledge of far wider application than merely to the organisms or disease initially studied. In the early 1940s there was a major effort at the Rockefeller Institute to develop a vaccine against pneumococcal pneumonia. While Avery and his collaborators did not succeed in producing an effective vaccine, they did discover during these studies that DNA was the chemical basis of heredity<sup>63</sup>. Science too may have its parables.

I thank Ms Yvonne Kress for providing the electron micrographs, and Drs L. Miller, J. Remington, M. Rifkin, M. P. Cunningham, J. Doyle and C. G. D. Brown for helpful discussions. I am indebted to Drs Herbert Tanowitz and Murray Wittner for involving me in the world of parasites and for many stimulating discussions.

# Magnetostratigraphy, biostratigraphy and geochronology of Cretaceous–Tertiary boundary sediments, Red Deer Valley

J. F. Lerbekmo\*, M. E. Evans† & H. Baadsgaard\*

\*Department of Geology and †Department of Physics, University of Alberta, Edmonton, Canada

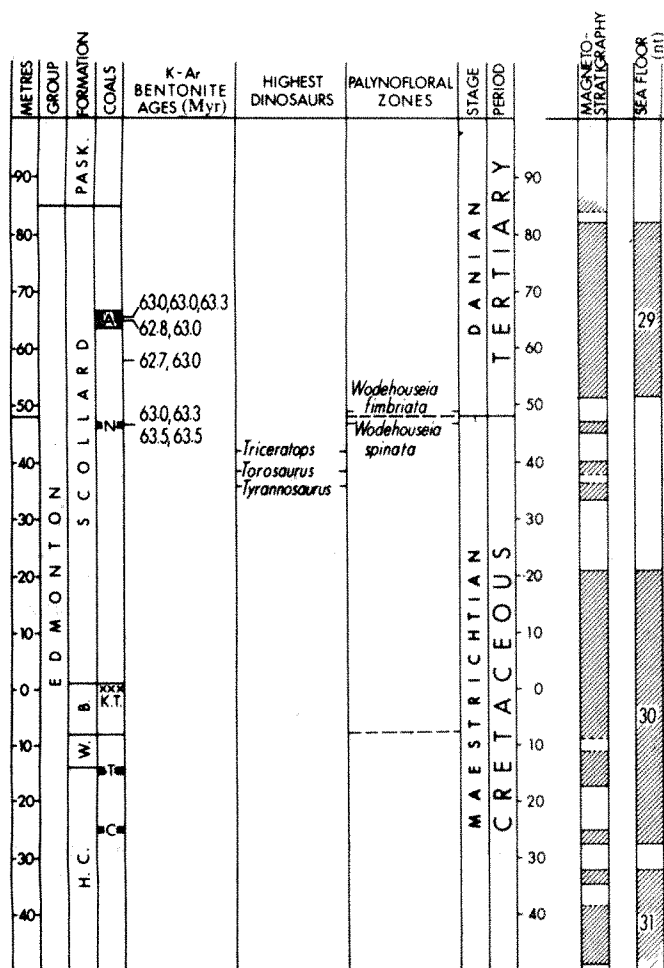

*Integrated magnetostratigraphic and biostratigraphic data for continental Cretaceous–Tertiary boundary sediments in Alberta allow a correlation with recognised sea floor magnetic anomalies 29 and 30. When compared with data from the marine Gubbio section in Italy, the correlation indicates that extinction of the dinosaurs on land was synchronous with foraminiferal extinctions in the sea which are equated with the Cretaceous–Tertiary boundary. We advocate that the base of anomaly 29 be tentatively accepted as the best worldwide physical approximation of the Cretaceous–Tertiary boundary. Eleven K–Ar dates on bentonite sanidines near this boundary yield a mean age of  $63.1 \pm 0.5(2\sigma)$  Myr.*

THE applicability of geomagnetic polarity reversals to worldwide stratigraphic correlation of sedimentary rocks has become accepted in the past few years. Interest in this application of 'magnetostratigraphy' is shown by the number of recent papers presenting slightly different polarity scales for the Mesozoic and Cainozoic<sup>1–3</sup>. Limitation of the accuracy of these scales is largely due to the scarcity of good radiometric dates.

The global demarcation of boundaries between major geological time units is very important. The Mesozoic–Cainozoic

boundary has caused a good deal of interest because of the evidence of worldwide extinctions and rapid evolutionary rates at this time. The organisms affected ranged from the largest to some of the smallest of the marine fauna (marine reptiles, ammonites, Foraminifera), and also included the largest continental animals, the dinosaurs, as well as some land flora. The search for causes of such widespread biotic changes has brought to light a large number of plausible explanations<sup>4</sup>. The choice between sudden catastrophic extraterrestrial events (supernovae), and somewhat slower terrestrial processes (global climatic changes), is hampered by the lack of sufficiently accurate and universally applicable chronological data on the contemporaneity of marine and continental extinctions. Correlation of the geomagnetic polarity reversals recorded in sedimentary rocks can provide the necessary accuracy on a worldwide scale. Two notable studies have been reported; one on a marine section near Gubbio, Italy<sup>5,6</sup>, the other on a continental section in the San Juan Basin of New Mexico, US<sup>7,8</sup>.

Accurate geochronology of the Cretaceous–Tertiary boundary is difficult because of a lack of explosive volcanicity in those parts of the world which were accumulating a record of fine-grained sedimentary deposits at this time. One of a few places where such volcanicity was prevalent, producing isotopically datable volcanic bentonites and tuffs, is the northwestern US and western Canada. This area was a swampy coastal plain flanking the western shore of a late Cretaceous mid-continental

**Fig. 1** Biostratigraphy, magnetostratigraphy and geochronology of the upper part of the Edmonton Group, Red Deer Valley, Alberta. B., Battle; W., Whitemud; H. C., Horseshoe Canyon; A., Ardley; N., Nevis; K.T., Kneehills Tuff; T, Thompson; C, Carbon. Cross-hatching denotes normal polarity intervals; dashed boundaries are more tentative than the solid line boundaries.

epieiric seaway with an active volcanic area further to the west. On this fluvial-deltaic lowland lived two of the greatest and the last of the dinosaurs, *Tyrannosaurus* and *Triceratops*.

We report here a study of geomagnetic polarity and K-Ar dating compared with dinosaur occurrences and recently published palynologic studies, carried out on an essentially conformable sequence of mudstones, sandstones, coals and volcanic ashes which encompasses the Cretaceous-Tertiary boundary. One aim of such a study is to obtain reliable dates from a section in which particular sea floor magnetic anomalies can be recognised, to provide data needed for improved temporal calibration of the older part of the marine sea floor anomaly sequence.

### Stratigraphy and palaeontology

The Red Deer Valley of south-central Alberta has long been known as a prime collecting area for late Cretaceous dinosaurs<sup>9</sup>; more recently it has been looked at by geochronologists<sup>10</sup> and palynologists<sup>11-13</sup>. The 100-m deep valley exposes within a distance of about 50 km the entire thickness (some 350 m) of the largely Maestrichtian Edmonton Group of nearly flat-lying fluvial-deltaic sediments (Fig. 1).

Detailed magnetostratigraphic analysis has been carried out on the upper 135 m of the Edmonton Group, concentrating particularly on the interval near the Cretaceous-Tertiary boundary as defined by a sudden major palynofloral change a few metres above the highest occurrence of dinosaur remains. The palynofloral change includes the abrupt disappearance of all species of *Aquilapollenites* (at least 10) except *A. spinulosus*, as

well as the disappearance of *Wodehouseia spinata*, *Cranwellia striata*, *Proteacidites* sp., and others. They are replaced by such species as *Wodehouseia fimbriata*, *Alnus trina* and *Carpinus subtriangula*<sup>13</sup>. An essentially identical palynofloral change takes place in Montana, Wyoming and the Dakotas at the Hell Creek (Lance)-Fort Union formational contact<sup>14,15</sup>. In this region the microfloral change also takes place a few metres above the highest occurrence of dinosaur bones, notably *Triceratops*.

In the Red Deer Valley of Alberta the palynomorph break occurs within a 2-m interval centred 1.5 m above a 20 cm bentonite near the top of the Nevis Coal seam. The stratigraphically highest known dinosaur remains still in place in the Red Deer Valley area are part of a scattered skeleton of a large carnivorous dinosaur in Sec. 10, Tp. 34, Rge. 22 West of the 4th Mer. This is the specimen first located by C.M. Sternberg in 1946 and recorded in his field notes as a scattered and broken skeleton of ?*Tyrannosaurus*. He collected part of a skull of a *Triceratops* recorded as occurring 20 feet higher and about 200 yards north of the tyrannosaurid. These specimens have been more recently classified as *cf. Tyrannosaurus rex* and *Triceratops albertensis*, respectively<sup>13</sup>.

The elevation of the *Tyrannosaurus* skeleton was apparently determined by Sternberg's party with an aneroid barometer, and the stratigraphic position determined by fitting this elevation into a more completely exposed section about 1 km to the south. Unfortunately, an error must have been made and the skeletons were inadvertently placed too high (stratigraphically) with respect to the Kneehills Tuff and the Ardley Coal seam. The portion of the tyrannosaurid which is still in place has been relocated and its stratigraphic position redetermined by one of us (J.L.). It lies 10.5 m below the top of the Nevis Coal seam. One assumes that the 20 feet stratigraphic separation between the two skeletons recorded by Sternberg is approximately correct inasmuch as the two sites are very close. The *Triceratops* is thus placed ~4.5 m below the Nevis Coal and 6 m below the Cretaceous-Tertiary palynomorph break. This *Triceratops* skull position is still the highest that we know to have been recorded in Canada.

In the Hell Creek Formation type area in east-central Montana at least three *Triceratops* skeletons have been recovered from an interval reported to be 9-17 m below the top of the Hell Creek Formation<sup>13</sup>. In the same area, two of us (J.L. and H.B.) found unreworked dinosaur bones within 4 m of the base of the Z coal which marks the palynofloral change and the Hell Creek-Fort Union contact. The position of the highest dinosaur bones in the type area of the Lance Formation in south-east Wyoming is shown to be about 3 m below the same palynomorph change at a lignite taken to mark the base of the Fort Union Formation<sup>15</sup>.

### K-Ar geochronology

The portion of the stratigraphic succession near the sudden palynofloral change contains pyroclastic bentonite beds suitable for uncontaminated sampling. Four bentonite horizons (+17.5, +17, +11 and -1 m from the palynofloral change) yielded transparent, unaltered sanidine of the requisite amount and purity for precise K-Ar dating. Duplicate bentonite samples were taken of three of the beds, and the sanidine separates were further split into two grain sizes to check on analytical reproducibility. Heavy liquid and magnetic separation procedures, followed by hand picking, enabled sanidine separates of at least 99.5% purity to be obtained.

Argon was extracted from the samples by flux-fusion *in vacuo*, mixed with pure <sup>38</sup>Ar isotope dilutant and purified by hot sponge titanium. Ar isotopic analysis was carried out on a Micro-Mass 6 gas mass spectrometer operating in the dynamic mode. Mass discrimination was determined by measurement of pure air argon in sequence with the Ar determinations in identical analytical conditions. Potassium was determined by isotope dilution using 99+ % enriched <sup>41</sup>K as the tracer. Decay

**Table 1** Analytical results from K-Ar dating of bentonite sandine

Sample, elevation (m), mesh size	$^{40}\text{K}^*$ (p.p.m.)	$^{40}\text{Ar rad}$ $^{40}\text{Ar total} \times 100$	$^{40}\text{Ar}/^{40}\text{K}$	Date* (Myr)

\* Constants used:  $\lambda_B = 4.962 \times 10^{-10} \text{ yr}^{-1}$ ;  $\lambda_A = 0.581 \times 10^{-10} \text{ yr}^{-1}$ ;  $^{39}\text{K} = 93.2581 \text{ at.}\%$ ;  $^{40}\text{K} = 0.01167 \text{ at.}\%$ ;  $^{41}\text{K} = 6.7302 \text{ at.}\%$ .

constants for  $^{40}\text{K}$  and natural potassium abundances used in computations are those recommended by Steiger and Jager<sup>16</sup>.

The analytical results are given in Table 1. Using 68 Myr for the age of the base of the Edmonton Group<sup>17</sup>, the average rate of sedimentation for the Group is about 65 m per Myr; thus the upper bentonite horizons dated should differ in age from the lower horizon by about 0.25 Myr. This span is within the overall error of the K-Ar determinations, and the dates are averaged to give  $63.1 \pm 0.5(2\sigma)$  Myr. Taking into account  $2\sigma$  errors (precision) in the K-determination ( $\pm 0.8\%$ ), the Ar-determination ( $\pm 0.6\%$ ), the  $^{38}\text{Ar}$ -spike volumes ( $\pm 0.4\%$ ) and the decay constants ( $\pm 1.7\%$ ), the K-Ar date for the horizon of palynofloral change in the Red Deer section is  $63 \pm 2$  Myr. Considering indeterminant sources of error, such as sample quality and analytical manipulations, the  $\pm 2$  Myr should probably be at least  $\pm 3$  Myr.

Careful optical assessment of sample purity showed essentially equal purity for fine- and coarse-grained splits of the sandine samples. Yet the K content (see Table 1) is invariably lower for the fine-grained fraction. The fine-grained fraction may be naturally lower in potassium, but the possibility of undetectable lower-K 'contamination' remains.

## Palaeomagnetic data

Approximately 600 samples were collected from some 170 stratigraphic levels (sites) covering 135 m of section. Normally three or four samples were taken at each site, occasionally more. Although the average vertical spacing is thus about 1 m, it varies from 3 m to 10 cm. Closer spacings are associated with polarity boundary levels, and were obtained after examination of preliminary samples. Samples are one-inch cylinders obtained by percussion coring.

The great majority of the remanence measurements were made with a Digico 'complete results' magnetometer, but a Schonstedt SM1 magnetometer was used for a few early measurements. Apart from the Kneehills Tuff and one other volcanic tuff bed, intensities of magnetisation were weak—generally below  $1.0 \times 10^{-6} \text{ e.m.u. cm}^{-3}$ . Routine alternating-field (a.f.) demagnetisation was carried out using the apparatus as described by McElhinny<sup>18</sup>. Completely standardised demagnetisation steps were not used as the material was variable, but peak fields of 75 and 100 Oe were most commonly used. Directional behaviour during progressive magnetic cleaning was highly variable, some specimens being relatively stable and others exhibiting large erratic angular changes. The least stable samples were eliminated by rejecting those associated with  $d\theta/dH > 0.5^\circ \text{ Oe}^{-1}$ , which reduces the data set to 455. The remaining remanence vectors represent 155 stratigraphic horizons and have been analysed as follows. The virtual geomagnetic pole (VGP) corresponding to each direction was calculated and compared to the well-established Upper Cretaceous-Lower Tertiary palaeomagnetic pole for North America (80–40 Myr,  $186^\circ \text{E}$ ,  $73^\circ \text{N}$ ,  $N = 11$ ,  $k = 51$ ,  $\alpha_{95} = 6^\circ$  (ref. 19). The angular differences between this pole and each VGP are here called 'polar angles' and are represented in Fig. 2 by the cosine of the polar angle.

Even after rejecting the most unstable material, considerable scatter remains. However, this scatter is not simply random noise—it is evident from Fig. 2 that a stratigraphic zonation exists. We argue that the profile represents a sequence of normal and reversed magnetozones but that secondary magnetic components acquired during the Brunhes epoch mask, to varying degree, the primary remanence of the reversely magnetised strata. An identical situation was recently described by Hillhouse *et al.*<sup>20</sup>. We adopt a modified version of their procedure

**Fig. 2** Magnetostratigraphy of the upper part of the Edmonton Group, and proposed correlation with sea floor magnetic anomalies (Kneehills Tuff is stratigraphic datum as in Fig. 1). See text for geomagnetic polarity assignment procedure. R, reversed; I, indeterminate; N, normal; RDV, Red Deer Valley; SF, sea floor.

for assigning polarity, namely: if all the VGPs at a given site have polar angles less than  $60^\circ$  the site is regarded as normal. If at least one VGP at a site has a polar angle greater than  $120^\circ$  the site is reversed. All other sites are regarded as indeterminate. Hillhouse *et al.* point out that these rules deliberately seek out reversed horizons and this is consistent with the hypothesis that these zones tend to be eliminated by recent magnetic overprinting. Indeed, it is still possible that certain indicated normal sites consist of entirely overprinted material, whereas the same is very unlikely to be true for reversed assignments. The choice of  $60^\circ$  as a cut-off value is arbitrary—we use it because it divides each palaeo-hemisphere in half. This procedure leads to the polarity profile shown in Fig. 2.

## Discussion

In Fig. 2 we have attempted to match the Red Deer Valley magnetozones with numbered sea floor anomalies. Recently published polarity scales place the Cretaceous–Tertiary boundary near the base of anomaly 29 (refs 1–3). The fairly long normal polarity zone which embraces the Ardley Coal seam (Fig. 1) thus corresponds to anomaly 29. The other relatively long normal zone (which includes the Kneehills Tuff) is then equivalent to at least part of anomaly 30, and our data suggest that the reversed magnetozones between 29 and 30 contains several short normal intervals.

It is more difficult to identify the short reversed interval which seems to be accepted as a diagnostic marker between anomalies 30 and 31. We have strong indications of at least two comparatively short reversals, either of which would seem to qualify. The lowermost reversal leads to the best relative time span for anomaly 30 versus anomaly 29 according to sea floor data<sup>1–3</sup>. Our measurements do not go low enough to enable us to use data from strata equivalent to anomaly 31. In the Gubbio marine section, the sampling interval of Roggenthen and Napoleone<sup>21</sup> allows several short reversals. The scale of the Lowrie and Alvarez<sup>6</sup> diagrams for the same section makes it difficult to assess their sampling interval, but the reversed zone they have located seems rather high in the section and may correspond to one of our two higher ones.

The presented pattern may still be somewhat oversimplified because we have not placed much weight on several possible short polarity intervals which are represented by more than one site in the unscreened data and are likely to be real, but may represent local geomagnetic 'excursions'.

One or more short normal polarity intervals below anomaly 29 seem to have shown up in other recently published results. Keating *et al.*<sup>22</sup> show a short normal in what may be this reversed zone at DSDP site 208. The data of Butler *et al.*<sup>7</sup> from New Mexico could also be differently interpreted by re-assigning the normal magnetozones they have called 28 to anomaly 29. This would allow correlation of the short normal they have called 29 with our short normal(s) in the reversed zone below 29 (Fig. 3). This re-assignment also removes the palaeontological discrepancies between the New Mexico, Alberta, and Gubbio, Italy sections with respect to the Cretaceous–Tertiary boundary and anomaly 29. Also, because the Cretaceous–Tertiary boundary in the Red Deer Valley is just below the base of anomaly 29 (Fig. 1), this assignment would fit Powell's<sup>23</sup> placement of the boundary in the San Juan Basin in his Kimbeto Member of the Ojo Alamo Sandstone = 'upper conglomerate' of Butler *et al.*<sup>7</sup>. Alternatively, the boundary may well be as low as the unconformity at the base of the conglomeratic member, as suggested by others<sup>24,25</sup>. Whichever is correct, we agree with Butler *et al.* that the palaeomagnetic evidence suggests the time breaks in the section measured by them must be relatively short.

Considering the rate of sedimentation of the Scollard Formation to be representative of that of the Edmonton Group (about  $65 \text{ m Myr}^{-1}$ ), one average metre represents about 15,000 yr. A check on the validity of this figure may be made using the approach of Kent<sup>26</sup>. The thickness of the reversed magnetozones between anomalies 29 and 30 in the Scollard Formation is 30 m.

## Tarling and Mitchell

Fig. 3 Suggested correlation of the Red Deer Valley section with the San Juan Basin section and the polarity time scale of Tarling and Mitchell. Dashed tie lines are correlations made by Butler *et al.*<sup>7</sup>. Solid tie lines and anomaly numbers in brackets are correlations suggested in the text. Diagram modified from Butler *et al.*<sup>7</sup>.

This represents a time span of 470,000 yr according to the latest polarity time scale<sup>3</sup>, providing a calculated sedimentation rate of  $63.7 \text{ m Myr}^{-1}$  or  $15,700 \text{ yr m}^{-1}$ . Thus the last dinosaur remains in Alberta were buried about 120,000 yr before the beginning of anomaly 29, and the discrepancy in time between the apparent dinosaur and palynofloral extinctions in this area is about 90,000 yr.

The marine foraminiferal extinctions marking the Cretaceous–Tertiary boundary in the Gubbio section in Italy occur at the base of the *Globigerina eugubina* zone which has been shown to be about 1.5 m below the base of anomaly 29 (ref. 21). Using a mean value of  $6.5 \text{ Myr}$  for the time span of the Maestrichtian<sup>5</sup>, the sedimentation rate for the Maestrichtian part of the Gubbio section is about  $12 \text{ m Myr}^{-1}$ . The rate calculated for the reversed magnetozones between anomalies 29 and 30 is  $12.8 \text{ m Myr}^{-1}$  (ref. 26). Therefore, the time interval between the Cretaceous–Tertiary boundary (based on foraminiferal changes) and the beginning of anomaly 29 was also about 120,000 yr. If our positioning of the base of anomaly 29 in the Red Deer Valley is correct, the foraminiferal Cretaceous–Tertiary boundary and the extinction of the dinosaurs are calculated to be very close in time. Uncertainties in sedimentation rates leave room for some deviation from exact synchronicity. An error in sedimentation rate of as much as 25%, which seems highly unlikely, would produce a maximum difference of about 100,000 yr. Similar studies need to be made on the marine reptilian and ammonite extinctions, but our data indicate approximate synchronicity between at least some marine and continental faunal extinctions at the end of the Cretaceous, by whatever cause.

As the evidence for dinosaur, foraminiferal and floral crises is present just below anomaly 29, it is advocated that the base of anomaly 29 be tentatively accepted as the best global physical approximation of the Cretaceous–Tertiary boundary.

We thank C. Singh for palynofloral identifications in our Hell Creek area samples. The study was supported by grants from the NRC and the Department of Energy, Mines and Resources of Canada.

# Observations of seafloor spreading in Afar during the November 1978 fissure eruption

P. Allard & H. Tazieff

Centre des Faibles Radioactivités, Research group on Volcanology, CNRS, 91190 Gif sur Yvette, France

D. Dajlevic

Service Technique Etudes de Pollution Atmosphérique et Minière, CEA, DPr, CEN, Saclay BP no 2, 91190 Gif sur Yvette, France

*In November 1978 a telluric crisis was recorded in the Republic of Djibouti, in connection with the opening of new distensive fractures in the Asal graben, the southernmost axis of the seafloor spreading in Afar. A short fissure eruption (7–14 November 1978) developed which allowed interesting observations of ridge-type volcanism and gas composition, and accurate measurement of seafloor spreading in Afar for the first time.*

It has been known since the early seventies<sup>1</sup> that the so-called 'Afar triangle' can be divided into two quite different structural units: (1) the Red Sea–Gulf of Aden megastructure (NNW and WNW trends respectively) which belongs to the mid-oceanic ridge type and corresponds to the active boundary between the parting Arabic and African plates, temporarily emerged in Afar; and (2) the northern end of the continental Great Rift Valley of East Africa.

The small Asal graben, approximately 40 km across and 12 km long, located between Asal Lake (155 m below sea-level) and the Gulf of Tadjoura, is the southernmost axis of the present seafloor spreading in Afar<sup>2</sup> (Figs. 1 and 2). The extremely young age of both volcanic products and tectonic manifestations (faults, uplifts) in the Asal graben<sup>3</sup> suggested that a geodimetric network should be set up in that area. The network was positioned by the Institut Géographique National in 1973 over the active axis to measure any increase in distance between the two drifting plates<sup>4</sup>.

## The fissure eruption

On 6 November 1978, a series of more than 800 earthquakes was recorded by the Arta seismographic observatory, some of them reaching a magnitude of 3.3 and an intensity high enough to alarm people in the city of Djibouti (70 km away). The actual eruption started the next day and lasted exactly one week.

A set of two dozen parallel normal faults was observed in a belt more than 1500 m wide in the axial area. Some of the faults reached 10 km long. The general fault direction was 300–320° (NNW), that is, parallel to the Red Sea tectonic trend. No significant lateral shifting was detected. The spacing between fault lips varied from a few tenths of a millimetre to more than a metre. The maximal throw observed was more than 0.5 m. The

whole set constituted a graben the depth and width of which can easily be determined by new geodimetric measurements. The increase in distance between the African and Arabian plates, roughly the sum of each fault width, can be determined exactly.

This event supports the hypothesis that the seafloor spreading mechanism works by sudden jerks, occurring a few times per century, rather than by a continuous smooth distension<sup>5</sup>. Average rates of seafloor spreading in the Asal rift area<sup>5</sup> should be referred to in terms of 1.5 m per century rather than 1.5 cm per yr.

The fissure eruption developed over a 0.75-km long segment of one of the normal faults, directly on the active axis. We called it 'Ardoukoba' (slope down, in Afar language) after the place name<sup>6</sup>. It was exclusively effusive and no actual explosions occurred: the only comparatively violent gas exhausting phenomena were lava fountains, which were generally 20–100 m above lava level. Lava flows spread rapidly over the depression. A lava pool developed, together with the building

Fig. 1 Location of the Asal rift in the Afar depression. Black areas are zones of generation of new oceanic crust.

Analysed by gas chromatography in helium with a catharometer cell. H<sub>2</sub> was detected in argon and H<sub>2</sub>S using a flame ionisation detector. H<sub>2</sub>O was determined by weighing. Measurements were from flask samples from flowing lava at 1,070 °C. ND, not determined.

up of a steep spatter rampart, 40 m high, erected on the fracture's lips as an oblong crater.

For the first few days of the eruption, the boiling lava pool had a nearly 2,000 m<sup>2</sup> surface, which was continuously overturned by the fountaining. The violence of the phenomenon prevented us from reaching the crater lip to sample eruptive gases and we had to wait for the last phase of the eruption before we could do so. A plume, the velocity of which was estimated at 10 m s<sup>-1</sup>, escaped from this crater. From 12 November the lava pool surface was restricted to 400 m<sup>2</sup>. The eruption ended on 14 November with a short, more explosive phase. The total gas output for the duration of the eruption (six effective days) is evaluated as 6 × 10<sup>9</sup> m<sup>3</sup>.

## Sampling

Gas samples were collected on the fracture on 13 November from lavas flowing out of the crater (temperature = 1,070 °C). Severe conditions restricted numbers of sampling to four only. More numerous (but less representative) samples were collected on 14 November from cracks in recent cooling lava flows. Gases were collected in evacuated glass flasks, containing either an alkaline solution or P<sub>2</sub>O<sub>5</sub> dessicator, connected to a 1.5-m long silica pipe. The alkaline-type flask showed the gas to be considerably mixed with air. Therefore, we also used a technique which allows the gas sample to remain in the same dilution as the plume, preserving the gaseous ratios. It was analysed with a high sensitivity (<1 p.p.m. for most gases investigated): the previously dehydrated gases are inspired by a peristaltic pump, stored in a Teflon bag and then immediately analysed by specific reactive 'Dräger' tubes.

Temperature measurements were taken simultaneously using a chromel-alumel thermocouple (±1 °C). Locations, temperatures and gas compositions are reported in Tables 1 and 2.

## Results

Air admixed with the magmatic gas found between the flowing lava and the upper solidified crust through which we sampled. Atmospheric values for N<sub>2</sub>/O<sub>2</sub> + Ar ratios, calculated from the O<sub>2</sub> + Ar contents in the four glass flasks, assuming that all Ar comes from air contamination, yield an excess nitrogen which either corresponds to a true magmatic excess or reflects a partial oxidation of the gas by atmospheric oxygen.

The gases were found to be richer in sulphur than carbon. The C/S atomic ratio (0.2) is lower than that typical of high temperature basaltic gases sampled from central vents (1.5 ± 0.3)<sup>7</sup>. Otherwise, similar C/S ratios have been found in gases sampled from early degassed basalts in Hawaii<sup>8</sup> and particularly from comparable lava flows from Mt Etna<sup>9,10</sup> or the Surtsey eruption (1966–67 samples)<sup>11</sup>. This lower ratio may be typical of a later degassing stage of the lava. Conversely the 14 November gas samples (evacuated flask samples and Teflon bag samples), collected from cooling lavas at sub-solidus temperatures are richer in CO<sub>2</sub> than in SO<sub>2</sub>, a feature more characteristic of gases exsolved from solidifying hot rocks. In these samples H<sub>2</sub>S is also rich relative to SO<sub>2</sub>.

CO/CO<sub>2</sub> ratios are in the range 1.3–4.2 × 10<sup>-2</sup>. Experimental data<sup>12</sup> showed that: (1) the oxidation state of a high-temperature gas phase is consistent with the oxygen fugacity in the melted basalt; (2) the CO/CO<sub>2</sub> ratio is the most reliable redox ratio, compared to H<sub>2</sub>/H<sub>2</sub>O or H<sub>2</sub>S/SO<sub>2</sub>, and is more sensitive to oxidation and to secondary gains or losses caused by condensations, reactions or additions.

Under a pressure of 1 atm and collection temperature (1,343 K) conditions, the oxygen partial pressure in equilibrium with CO and CO<sub>2</sub> can be calculated from:

$$\log p_{O_2} = 2 \left( \frac{\Delta G_T^\circ}{9.150T} - \log \frac{p_{CO}}{p_{CO_2}} \right)$$

where  $\Delta G_T^\circ = -135,330 + 41.74T$  (calculated from standard thermodynamic data<sup>13</sup>).

Table 1 lists the four p<sub>O<sub>2</sub></sub> values obtained, and the mean oxygen partial pressure of the gas is found to be p<sub>O<sub>2</sub></sub> = 10<sup>-9.40</sup> atm. This is in remarkable agreement with the p<sub>O<sub>2</sub></sub> value in the Erta Ale gases (Afar)<sup>12</sup>, and consistent with the oxygen fugacities measured or deduced from mineral assemblages in basalts<sup>14,15</sup>.

Water vapour is generally the major gas present and often amounts to 80–90 mol % of the total, even in higher quality samples collected previously<sup>12</sup>. The interesting point in the present results is the relative deficiency in H<sub>2</sub>O content of the Ardoukoba samples. The measured H<sub>2</sub>/H<sub>2</sub>O ratio (about 10<sup>-3</sup>) is not consistent with the mean p<sub>O<sub>2</sub></sub> calculated above: a p<sub>O<sub>2</sub></sub> of 10<sup>-9.4</sup> atm would lead to an equilibrium H<sub>2</sub>/H<sub>2</sub>O ratio of about 10<sup>-2</sup>. As water vapour clearly condensed inside the flasks during

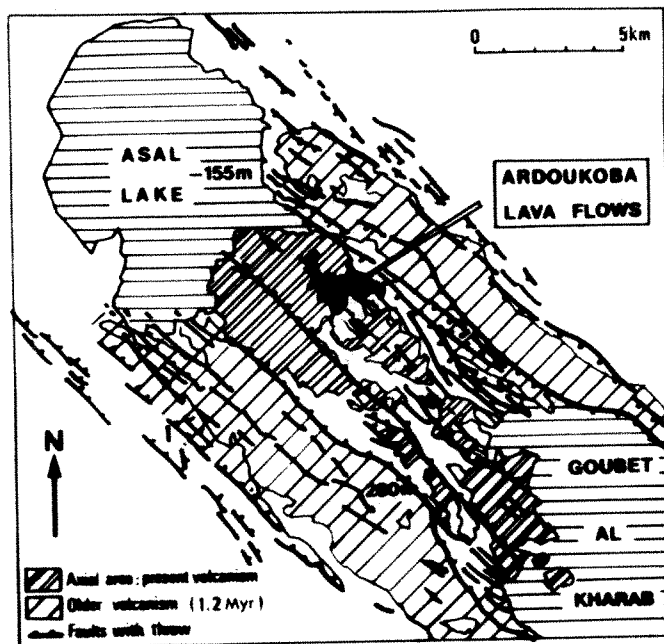

Fig. 2 Position of the Ardoukoba lava flows in the Asal rift.

Sublimates were analysed using an EDS. (Five analyses of green and white sublimates.) Measurements were from Teflon bag samples (810–910 °C).

sampling (temperature at the opened end of the sampling pipe reached more than 400 °C), we can be certain that no water vapour was lost through the flask's stopcock. We suggest two hypotheses to explain this discrepancy: (1) A partial oxidation of the initial H<sub>2</sub> occurs (1 mol % calculated from H<sub>2</sub>/H<sub>2</sub>O = 10<sup>-2</sup>), consistent with the partial deficiency in the O<sub>2</sub> contents when air contamination is calculated on the N<sub>2</sub> basis. (2) A preferential enrichment in H<sub>2</sub>O occurs by continuous adsorption on the dessicator in excess during the few seconds the flasks were open. If this were so, the equilibrium H<sub>2</sub>O contents might have been about five times less than they were actually found to be in the samples.

At present it is not possible to decide between these two hypothetical mechanisms, and they may have acted together. Also, the H<sub>2</sub>O content of the samples has to be considered as an upper limit to the water vapour fraction of these eruptive gases which therefore appear particularly anhydrous.

The HCl content in samples from cooling lavas (Table 2) is surprisingly low as it has been shown from many volcanoes that similar gases from early degassed lavas are generally more chloride-rich than those from central vents. Atomic Cl/S ratios in Ardoukoba gases are still lower than Cl/S ratios in gases collected from the Erta Ale lava lake (0.17) or from lava flows of the oceanic Surtsey eruption (0.03–0.5)<sup>11</sup>.

From the proximity of highly saline waters in Asal Lake (NaCl > 350 g l<sup>-1</sup>), 2 km away, and of seawater in the Ghoubet, 10 km away (Fig. 2), one could have expected a marine type

contamination of the magma and gases, the eruption point of which was situated about 100 m below sea level.

In fact, the collected samples appear rather lacking in vapour and chloride poor. Moreover, microprobe energy dispersion spectrometer (EDS) analyses of incrustation deposits from around the fuming points (Table 2) show no anomalous sodium enrichment and show also that these sublimates are particularly depleted in chloride, boron and magnesium.

The total lavas welled out by the eruption amounts to 16 × 10<sup>6</sup> m<sup>3</sup>, the average thickness of the 1.6 km<sup>2</sup> lava field being estimated at about 10 m. This highly fluid lava contains a high proportion of phenocrysts, mainly large crystals of plagioclase (bytownite) up to 4 cm long, and far less olivine and clinopyroxene. It is identical to the particularly plagioclase-rich basalts widely outcropping in the active part of the Asal graben<sup>5,16</sup> (Table 3).

## Discussion

Note that this short, but volumetrically important, eruption is similar to numerous recent ones, the evidence of which we observed in this area and throughout the whole northern and central Afar depression, and is probably representative of most of the fissure eruptions in rift areas. It is interesting as a reference for the so many, but invisible, submarine fissure eruptions. In particular, it is useful to compare the ratio of the massic gas and lava outputs with the volatile amounts trapped in fresh sub-oceanic basalts. 16 × 10<sup>6</sup> m<sup>3</sup> of solidified basalt with a density of 2.7 g cm<sup>-3</sup> yields 43 × 10<sup>6</sup> tons of lava discharged by the Ardoukoba eruption, and the mass of 6 × 10<sup>9</sup> m<sup>3</sup> of emitted gas, the density of which could be considered to be ~0.25 g l<sup>-1</sup> at 1 atm and 1,100 °C, is 1.5 × 10<sup>6</sup> tons. Then, the mass gas output amounts for 3% of the lava production. This is rather small, when compared with the recently measured gas discharge from other volcanoes<sup>17</sup>, which widely exceeds the initial volatile content the corresponding erupted magma could supply.

This leads us to consider that the magmatic reservoir from which the Ardoukoba eruption developed may have been a closed system. The relative 3% massic gas to lava output is scarcely a few times the volatile content in sub-oceanic ridge basalts<sup>18</sup>.

This low gaseous output, the particularly low water vapour content, the apparent lack of marine contamination which might have been expected, the short duration of the eruption and the highly crystallised state of the produced lava, make us think that the magma intrusion which supplied the Ardoukoba eruption was quite narrow and probably close to the surface, and hence reduced the disturbance the eruption could have brought about in the geological surroundings.

**Table 3** Chemical composition (wt % oxides) of the Ardoukoba lava and phenocrysts

	Lava flow	Pyroclastite	Olivine	Pyroxene	Plagioclase
SiO <sub>2</sub>	48.01	48.01	37.55	51.22	46.55

# Fluorine in Iceland and Reykjanes Ridge basalts

E. C. Rowe & J-G. Schilling

Graduate School of Oceanography, University of Rhode Island, Kingston, Rhode Island 02881

*Unlike chlorine and bromine, fluorine is not appreciably outgassed from basalts erupted above 500 m depth along the Reykjanes Ridge and subaerially over Iceland. The mantle beneath Iceland seems to be twice as rich in fluorine as the asthenosphere source of normal ridge basalts south of 61°N.*

OCEANS and atmosphere are generally accepted to have formed over geological time by the outgassing of volatiles from the Earth's interior during volcanism<sup>1</sup>. But very little is known about the abundance, distribution and relative fractionation of volatiles in the mantle. Nor do we fully understand the nature of the processes of transport and release of volatiles to the Earth's surface. The study of volatiles in lavas derived from the mantle is complicated by the tendency of such elements to be partly lost during the ascent of magmas, either before erupting at shallow depth under the sea or during subaerial eruption. Furthermore, volcanic gases collected near volcanic vents may not be juvenile, but partly or totally derived from fluids of meteoric origin. Thus, knowledge of the geochemical evolution of volatiles in the mantle has lagged behind that of the more refractory elements. The study of submarine basalts and basaltic glasses, pioneered by Moore<sup>2</sup>, has opened up new opportunities for the investigation of volatiles.

Unni and Schilling<sup>3</sup> have described the distribution of chlorine and bromine in basalts from the Reykjanes Ridge and Iceland, contrasting subaerial with submarine volcanism as affected by hydrostatic pressure. They found that both chlorine and bromine were drastically fluxed out from lavas erupted at depths of less than 500 m below sea level (approximately 50 bar hydrostatic pressure), coincident with the depth of extensive vesiculation of water observed in several instances<sup>2,4–8</sup>. Chlorine and bromine degassing occurs although neither of the two halogens is saturated in the silicate melt in the pressure-temperature conditions of eruption<sup>3</sup>. Fluxing of sulphur and selenium has also been observed at this depth<sup>7,8</sup>. Unni and Schilling<sup>3</sup> have considered the possibility of fluxing of chlorine and bromine as due to a strong tendency for these two volatiles to separate into the aqueous fluid phase relative to the melt during vesiculation, in accordance with the experimental partition data of Kilinc and Burnham<sup>9</sup>. However, the amount of water actually exsolving seemed to be insufficient, and CO<sub>2</sub> (and/or SO<sub>2</sub>) was invoked as an additional possible major flux carrier for outgassing chlorine and bromine.

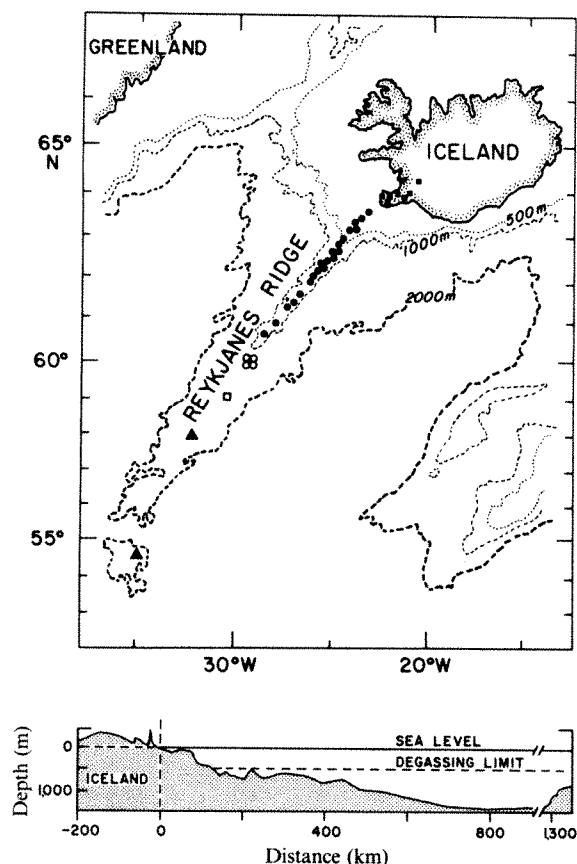

Fluorine, although another member of the chemically related halogen group, might be expected to behave differently in a silicate melt-aqueous fluid system. Its smaller ionic radius, 1.34 Å compared with 1.81 Å for chlorine and 1.96 Å for bromine, permits fluorine to substitute easily for OH<sup>–</sup> in hydrous minerals or melts<sup>10</sup>. The few experimental data available for partitioning of fluorine and chlorine between silicate melts and a co-existing H<sub>2</sub>O fluid phase at high temperature and pressure<sup>9,11</sup> suggest partition coefficients of 3:1 for fluorine in favour of the melt, but less than 1:30 for chlorine. The existing data are for granitic-type melts. As far as we know there is no corresponding data for melts of tholeiitic composition.

We report here the fluorine content of basalts from the Reykjanes Ridge-Iceland profile previously analysed by Unni and Schilling<sup>3</sup> for chlorine and bromine. This part of the Mid-Atlantic Ridge, as it shoals from 1,380 m to its subaerial expression in the south-west neo-volcanic zone of Iceland, affords an excellent opportunity to study the behaviour of volatile elements as a function of hydrostatic pressure. Locations and depths from which the samples were dredged are shown in Fig. 1. This area also spans from rare earth<sup>12</sup> and isotope data<sup>13,14</sup> two apparently separate and distinct mantle sources of magma with a zone of mixing between them. Furthermore, it has been shown<sup>3</sup> that chlorine and bromine variations along the Reykjanes Ridge-Iceland profile fit quite well a predictive model compounded from a curve of the distribution of large ion lithophilic trace elements (LILE) from two different adjacent mantle sources and their mixing, and a curve representing the degassing of a volatile from lavas derived from a single homogeneous mantle source as a function of decreasing hydrostatic pressure above 500 m of depth. The abundance of fluorine in the same basalt samples should not only reveal the distribution of fluorine along the Reykjanes Ridge and its extension beneath Iceland, but also yield useful information relevant to degassing mechanisms of the three halogens and their relative fractionation during degassing.

## The fluorine profile

Fluorine was determined by a specific ion electrode procedure adapted from the method of Ingram<sup>15</sup> for fluoride in silicate rocks, combined with the procedure of Huang and Johns<sup>16</sup> for fusion and preparation of sample solutions. The method was standardised against the literature values of Flanagan<sup>17</sup> for the rock standards AGV-1 and JB-1, and was reproducible to ±15 p.p.m. in the relevant concentration range. The samples are fresh basalts dredged from the axis of the ridge<sup>12</sup>, and analyses

were carried out on powders prepared for the most part from the variolitic zone of pillows, and a few from glasses from pillow rims. A summary of individual fluorine concentrations in pillow basalts from the Reykjanes Ridge and Iceland is given in Table 1, where they are compared with the chlorine values of Unni and Schilling<sup>3</sup> determined on the same samples.

**Fig. 1** The Reykjanes Ridge and Iceland, showing depth contours and sample locations. Cruise numbers are: ●, TR 101; ○, TR 41; □, GLJ; and △, TR 100; and subaerial samples are designated by ■.

The variation of fluorine content with latitude (Fig. 2) shows a progressive increase of fluorine towards Iceland. The fluorine profile resembles those of refractory incompatible trace element ratios such as  $[La/Sm]_{EF}$  (Fig. 2a), or of isotope ratios<sup>13,14</sup> of  $^{87}Sr/^{86}Sr$  or  $^{206}Pb/^{204}Pb$  and  $^{208}Pb/^{204}Pb$ . Furthermore, fluorine variation does not seem to be related in any simple way to Al, Mg, or Ca variation in these basalts along the Reykjanes Ridge–Iceland profile. Nor is it related to silica content, which remains constant at  $50 \pm 0.3\%$  in submarine samples and drops to 47–49% over Iceland (data not shown). Indices of major element fractionation such as  $\Sigma Fe/\Sigma Fe + Mg$  and  $Na_2O/CaO$  pass through a maximum over the Iceland shelf coincidental with the en echelon displacement of the ridge axis<sup>18,19</sup>, whereas fluorine continues increasing towards Iceland. These observations rule out the possibility of explaining the fluorine increase towards Iceland as being due to increasing fractional crystallisation or decreasing degrees of partial melting of a single mantle source toward Iceland (see for example refs 12, 20–22 for discussions on the subject).

In marked contrast to the other volatiles Cl, Br, S and Se, fluorine does not show any appreciable degassing above the apparent 500 m critical depth of extensive vesiculation of water vapour observed in several instances<sup>2,3,5,7,8</sup> (Fig. 2). Although fluorine follows the same trend as chlorine up to 63°N at depths

greater than 500 m, the fluorine content of basalts in the northernmost section of the profile remains high while chlorine decreases due to progressive degassing with decreasing depth of eruption<sup>3</sup>. The failure of fluorine to degas is further emphasised in Fig. 3, which compares variation of fluorine with variation in lanthanum, a refractory element; potassium, a less refractory element; and chlorine, a volatile element. For both lanthanum versus fluorine and potassium versus fluorine the Iceland field (subaerial) overlaps with the trend for the Reykjanes Ridge. But in the case of chlorine versus fluorine, the Icelandic field has moved down along the chlorine axis and is quite distinct from the Reykjanes Ridge basalts, because of the loss of chlorine during subaerial eruption<sup>3</sup>.

The relative fractionation of fluorine with respect to chlorine in the Reykjanes Ridge basalts is shown in Fig. 2, using Cl/F ratios from Table 1. The ratio increases on approaching land, apparently due to enrichment of the larger ion in the Iceland mantle source compared with the LILE-depleted asthenosphere. But at depths less than 500 m and in subaerial samples the ratio drops drastically because of the loss of chlorine with concurrent water vesiculation. From a maximum value of 1:1 the Cl/F ratio drops to about 0.1, or by approximately an order of magnitude.

\* Our precision for F analyses of standards AGV-1 and JB-1 were  $439 \pm 19(1\sigma)$  and  $365 \pm 9(1\sigma)$ , respectively. Corresponding recommended values are  $435 \pm 20$  and 360 (ref. 17).

† Distance SW along the Reykjanes Ridge Axis; taken equal to zero at the SW tip of the Reykjanes Peninsula.

‡ Cl values from Unni (ref. 46).

Yet, despite the evidence suggesting absence of degassing of fluorine from the Reykjanes Ridge basalts, fluorine is often found to be present in volcanic gases and emanations.

Measurements of the F/Cl ratio in gases from Hawaiian volcanoes range from 0.3<sup>23</sup> to 0.003<sup>24</sup>. Moreover the incidence of fluorine poisoning in grazing livestock following a major Icelandic eruption has been directly correlated with wind direction, distance from the eruption vent, and thickness of tephra layers<sup>25</sup>. Thorarinnsson<sup>26</sup> describes measurements of 350 p.p.m. fluorine in ash particles less than 0.06 mm in diameter compared with 50 p.p.m. in an 0.25 mm fraction, such enhancement has been interpreted<sup>27</sup> as indicating adsorption of gaseous HF on the surface of the ash during its eruption. Thorarinnsson<sup>26</sup> has estimated that at least  $3 \times 10^4$  tons of fluorine were discharged with the tephra of the Mt Hekla eruption in 1970.

**Fig. 2** Comparison of the F profile (b) with the La/Sm enrichment factor ratio (a), Cl (c), and the Cl/F ratio (d).  $\circ$  are anomalously low in Cl (and also Br) but not in F or refractory elements. Morphologically, they are rounded vesicular basalts (not pillows), and represent probably lava erupted subaerially, subsequently eroded by wave action during subsidence (or submergence). The low Cl and Br, but not F nor LILE contents, seem to corroborate our observations made previously on ship.

Our evidence for the lack of any substantial fluorine degassing at eruption depths of less than 500 m along the Reykjanes Ridge would seem paradoxical. This is not the case. A simple calculation using the Rayleigh distillation equation<sup>28</sup> predicts that, if a maximum of 0.5–1.0% H<sub>2</sub>O vapour exsolved, the chlorine and fluorine concentrations of the vapour would be of the order of 5,000 p.p.m. and 70 p.p.m. (assuming vapour–melt partition coefficients of 30 and 0.33) respectively. The F/Cl ratio in the vapour would be 0.014, thus well within the range observed on land<sup>23,24</sup>. The fluorine content of the remaining magma would have increased only by 1 p.p.m. maximum, which is well within the analytical uncertainties.

The lack of appreciable outgassing of fluorine along the ridge may to some extent be further tested by comparing variation in fluorine with variation in a refractory lithophilic element which might vary coherently with fluorine. Data from the area of the Mid-Atlantic Ridge encompassing the Azores platform, a section well below the 500 m critical depth of degassing, indicate that fluorine and strontium, or fluorine and phosphorous do not fractionate appreciably relative to each other during partial melting or fractional crystallisation<sup>29,30</sup>. The two ratios remain constant despite clear evidence from <sup>87</sup>Sr/<sup>86</sup>Sr data<sup>31,32</sup> of a change in mantle source beneath the Azores. Figure 4 shows variation of the F/Sr and F/P ratios with distance along the Reykjanes Ridge–Iceland profile.

Equations for least-squares best-fit slopes are:

$$F/P = 3.28 \times 10^{-5} d + 0.289$$

$$F/Sr = 1.22 \times 10^{-4} d + 1.75$$

where  $d$ , the distance in km south-west along the Reykjanes Ridge axis, is set equal to zero at the south-west tip of the Reykjanes Peninsula on Iceland. In other words, both ratios remain essentially constant along the profile. The subaerial data are insufficient to establish any significant loss of fluorine. Even if the sample IC-17 (anomalously high in fluorine content) is not considered, the small drop in F/Sr and F/P ratios over Iceland would suggest a maximum loss of only 5–10%. We conclude from this and from the Cl/F ratio profile that unlike chlorine and bromine, fluorine does not appreciably degas from lava erupted subaerially or above the 500 m depth. A comparison of the maximum and minimum Cl/F ratios would indicate a relative

**Fig. 3** Comparison of F variation with La (refractory), K (less refractory), and Cl (volatile). —, Reykjanes Ridge submarine samples; ---, Icelandic subaerial field.  $\bullet$ , Iceland;  $\Delta$ , 63–64° N;  $\square$ , 62–63° N;  $\circ$ , 61–62° N; +, S of 61°.

fractionation of these two elements of at least a factor of 10 in the shallow water and subaerial basalts.

Yet, the Rayleigh distillation calculation previously discussed predicts only a 25% drop in the Cl/F ratio due to vesiculation of a maximum of 0.5–1% water vapour. The Cl/F ratio could be further reduced to 33% of the maximum observed, if up to 50% of the melt underwent shallow depth fractional crystallisation at the same time as vesiculation occurred. A fluorine bulk crystal–melt partition coefficient of 0.02 was used in the calculation<sup>30</sup>. Note also that these calculations are based on fluid–melt partition coefficients for granitic melts<sup>9,11</sup>. Unless in the case of basaltic melts such vapour–melt partition coefficients are significantly reduced for fluorine and increased for chlorine, vesiculation of a major gas phase other than H<sub>2</sub>O, such as CO<sub>2</sub>, would have to be invoked to account for the major Cl/F drop at less than 500 m depths, as suggested by Unni and Schilling<sup>3</sup> for chlorine alone. A corollary of the chlorine outgassing mechanism proposed for lava erupted above 500 m depth or subaerially is that emanated volcanic gas counterparts should have a Cl/F greater than unity. This seems to be corroborated by the Cl/F ratios of volcanic gases, which though quite variable, are usually greater than unity, and often greater than 10 (refs 23, 24, 33, 34). The preferential affinity of fluorine for the melt compared with chlorine might suggest a different structural model for the solubility of fluorine as opposed to chlorine in silicate melts, although Burnham's<sup>35</sup> solubility model would not support this.

### Fluorine content of the two mantle sources

As previously inferred, the fluorine distribution in the Reykjanes Ridge–Iceland basalts is consistent with Schilling's model<sup>12</sup> of two mantle sources for this region, one depleted in LILE and one more enriched, with an intermediate zone of mixing between them. The fluorine content in the section between 54° and 61°N (deep sea) averages  $114 \pm 24$  p.p.m. ( $1\sigma$ ), which may be taken as characteristic of mid-oceanic basalts derived from a LILE-depleted asthenospheric source. North of 63°N and including seven Icelandic tholeiites from the southwestern neo-volcanic zone, fluorine averages  $232 \pm 32$  p.p.m. ( $1\sigma$ ), with more scatter in subaerial than submarine samples. Fluorine between 61° and 63°N grades between the two levels in a manner grossly consistent with the mixing of two sources. These results suggest a 2–3 fold relative enrichment of fluorine in the mantle source of basalts from the Iceland platform over the source of the ridge south of 61°N.

An estimate of the fluorine content of the two mantle sources of this region may be made by assuming: (1) partial melting of 25–30% over the entire area to produce the magmas, and (2) a reasonable partition coefficient for fluorine between solid and melt during partial melting. Estimates of a fluorine partition coefficient can be made in two ways, considering that no experimental values are available. First, fluorine varies nearly coherently with strontium in the processes of partial melting and fractional crystallisation<sup>29,30</sup>. The strontium partition coefficient between basaltic groundmass and a number of minerals present as phenocrysts measured by Philpotts and Schnetzler<sup>36</sup> varies greatly, depending on the nature of the phenocrysts. Assuming that the two mantle sources under consideration were originally composed of a lherzolite containing 60% olivine, 20% orthopyroxene and 20% clinopyroxene, the bulk partition coefficient for strontium (and hence also F) between such an assemblage and the melt ( $D_{Sr}$ ) would be about 0.04 ( $D_F = D_{Sr} = 0.60 \times 0.01 + 0.20 \times 0.1 + 0.20 \times 0.06$ ).

Second, although the mineral phases of the mantle are speculative, judging from the fluorine value determined by Huang and Johns<sup>16</sup> for the geochemical peridotite standard PCC-1, a fluorine value of 13 p.p.m. would be anticipated for a residual peridotite which has been depleted in LILE by partial melting. Since  $D$  is defined as  $C_R/C_L$ , where  $C_R$  is the concentration in the solid residue after partial melting and  $C_L$  the concentration

in the melt, then, assuming 13 p.p.m. for  $C_R$  and a minimum of 100 p.p.m. F for  $C_L$  in the melt, a partition coefficient ( $D_F$ ) of a maximum of 0.13 would be obtained, which is not far from the partition coefficient for fluorine calculated from a lherzolite mantle model using strontium as an analogue.

The use of a reasonable partition coefficient of 0.06 for fluorine would suggest a fluorine content of  $74 \pm 10$  p.p.m. for the Iceland mantle source, and  $36 \pm 9$  for the LILE-depleted asthenosphere, assuming a degree of melting of 25–30% and using the partial melting equation of Schilling and Winchester<sup>37</sup>.

### Fluorine in basaltic glasses

We have also examined the possibility of fluoride exchange with seawater, either during submarine basalt formation at the time of quenching, during subsequent cooling of the pillow lava, during low temperature weathering, or during hydrothermal circulation. For this purpose the fluorine content of fresh glasses, glasses altered to various degrees, and a palagonite were compared with pillow interiors (mostly sampled within the variolitic zones). The samples were either from the same basalt pillow or from other pillow fragments recovered from the same station.

Table 2 summarises our results for fluorine in 15 glasses and a sample of palagonite removed from the glassy rim of a pillow basalt from dredge haul TR101-27D, and compares these concentrations with fluorine values of pillow interiors from Table 1. Five of the 15 glasses matched rock fluorine within analytical error and two more were only slightly higher. The others were enhanced in fluorine by a factor of 1.3–3.0, and the enrichment is not apparently related to depth of eruption, latitude or the quantity of fluorine in the corresponding crystalline samples. In no case was fluorine in glass significantly lower than in the more crystalline pillow interior. Several glass samples from one station showed highly variable enrichment in fluorine

content (TR101-27D). A similar increase in content in quenched glassy rims over more crystalline interiors has been observed for several volatiles other than fluorine, such as sulphur<sup>38</sup>, <sup>40</sup>Ar (ref. 39), and H<sub>2</sub>O (ref. 5).

† Pillow interior (mostly variolitic zone).

‡ s.g., Station glass (loose glass found in the dredge haul).

§ Rock values in parentheses are from a different pillow within the same station.

The cause of fluorine enhancement in some of these glasses is uncertain. There are several possibilities: (1) Incorporation of fluorine from seawater either during quenching or later by low-temperature weathering, would seem unlikely. The fluorine content of seawater is only 1.3 p.p.m. (ref. 40) while the content in pillow interiors is 82–270 p.p.m. Equilibrium of the glass with seawater would tend to reduce fluorine in the glass, if the partition coefficient previously discussed were to apply. (2) Entrapment of bubbles rising from the melt, as proposed by Moore and Schilling<sup>7</sup> for sulphur enhancement in glasses, might be considered. However, in the case of fluorine this explanation also seems unlikely, as first, we have shown that fluorine is not appreciably degassed from vesiculating lava and hence is not mobilised during vesiculation (see the previous calculation on distillation of fluorine), and second, the observed fluorine enhancement was not related to hydrostatic pressure. (3) Fluorine could have been lost from pillow interiors, rather than enriched in the glassy rims. The mechanism of Corliss<sup>41</sup>, by which incompatible elements are concentrated in residual interstitial liquid in a crystallising melt—to be subsequently removed by hydrothermal waters circulating through micro-cracks and fissures, is supported by finding fluorine as one of the elements enhanced in interstitial melts from the Alae Lava Lake of Hawaii<sup>42</sup>. Fluorine data on hydrothermal solutions such as found in the Galapagos Region<sup>43</sup> could be a test of this possibility, when available. Clearly, more information is needed to resolve the question of high glass/rock ratios for fluorine.

## Conclusions

Fluorine does not outgas like chlorine and bromine from submarine lavas erupted at a depth of less than 500 m, the depth of rapidly increasing vesiculation. While fluxing by vesicle-forming major volatiles, such as H<sub>2</sub>O and/or CO<sub>2</sub>, seems to explain the outgassing of chlorine and bromine at shallow depth, such a mechanism is ineffective in removing appreciable quantities of fluorine. Our observations of outgassing of halogens and relative fractionation of chlorine and fluorine during intense vesiculation

at depth shallower than 500 m are also consistent with experimental partition data for the relative distribution of fluorine and chlorine between silicate melts and a co-existing aqueous phase. The proposed outgassing model is also consistent with the contrasting Cl/F ratios less than unity in outgassed lavas and greater than unity in volcanic gas counterparts usually reported. The contrasting outgassing behaviour of fluorine and chlorine (and bromine) emphasises the need of establishing whether a distinct structural model for the solubility of fluorine in silicate melts as compared with chlorine and bromine is required.

The distribution trend of fluorine in basalts from the Reykjanes Ridge and Iceland profile is consistent with the hypothesis of two mantle sources and their mixing for the origin of basalts of this area. The mantle source of the Iceland basalts seems to be enriched by approximately a factor of two over the source of the ridge basalts erupted south of 61°N.

An explanation for our finding of fluorine enrichment in some glass samples over more crystalline pillow interiors (variolitic zone) will require further information.

O'Hara<sup>44</sup> has considered extensive and long-lived contamination of Icelandic magma chambers by previously erupted basalts which may have been hydrothermally altered by circulating seawater. We cannot comment on this mechanism from our fluorine data which does not include hydrothermally altered basalts. However, we note that the <sup>207</sup>Pb/<sup>204</sup>Pb versus <sup>206</sup>Pb/<sup>204</sup>Pb trend previously observed for the Iceland-Reykjanes Ridge profile<sup>14</sup> does not point towards estimated lead isotope ratios for seawater<sup>45</sup>, as would be expected if the O'Hara model were to be applicable to this region.

# t-Haplotypes of the mouse may involve a change in intercalary DNA

Mary F. Lyon, E. P. Evans\*, Susan E. Jarvis & Irene Sayers

MRC Radiobiology Unit, Harwell, Didcot, Oxon, UK

\* Sir William Dunn School of Pathology, South Parks Road, Oxford, UK

*The naturally occurring t-haplotypes of the mouse exhibit a set of peculiar genetic properties, including strong suppression of crossing over in the segment of chromosome 17 between the loci of T and H-2. Study of the genetics of mutant haplotypes suggests that the observed effects on meiosis and embryonic development may be due to an altered form of intercalary DNA (iDNA) in the relevant chromosomal region (band 17B).*

THE t-haplotypes of the mouse<sup>1-4</sup> occur commonly in the wild and thus must be considered part of the usual mouse genome. Furthermore, they are located near to the major histocompatibility complex (H-2 complex) on chromosome 17, thereby inviting speculation concerning any possible evolutionary or other genetic significance of this close association<sup>5,6</sup>. Their properties include homozygous lethality and various effects when heterozygous, including enhancement of the effect of the mutant gene for brachyury, T, sterility or segregation distortion in males, and strong crossover suppression in chromosome 17.

The nature of the genetic change in t-haplotypes remains unknown. They are thought to involve some kind of chromosomal changes, but there is no evidence for major structural rearrangements such as inversions<sup>7</sup>, and no indication that rDNA is involved<sup>8</sup>. We suggest here that t-haplotypes involve a change in moderately repetitive DNA (iDNA) intercalated between the structural genes in the segment of chromosome 17 occupied by the haplotypes, extending approximately from the locus of brachyury, T, to the H-2 complex (Fig. 1). This suggestion arises from a study of the retention, loss or alteration of the various properties in 'mutant' t-haplotypes which have been derived from naturally occurring ones by crossing over or other means, and we regard it as a development of our earlier suggestions that t-haplotypes involved 'heterochromatin' (ref. 9) or changes in interstitial heterochromatin<sup>10</sup>.

Heterozygotes for brachyury T typically have short tails, but t-haplotypes interact with T, so that T/t heterozygotes are tailless. When homozygous, naturally occurring t's are lethal or semi-lethal during embryogeny, and fall into six lethal complementation groups, with partial complementation between groups in terms of viability<sup>1</sup>. Surviving t<sup>x</sup>/t<sup>y</sup> males (where t<sup>x</sup> and t<sup>y</sup> are from different groups), and also males homozygous for semi-lethals, are sterile. Furthermore, males heterozygous for a single t-haplotype, that is, +/t or T/t, although fertile, transmit t to the offspring with an abnormal frequency, usually having a large excess of t-carrying young. In addition, natural t-haplotypes strongly suppress crossing over in both sexes in the segment of chromosome 17 extending from T to H-2.

A further characteristic is that of mutating to other forms, with loss or occasionally gain of one or more of the other properties. This 'mutation' is usually, but not always, accompanied by crossing over within the region of strong crossover suppression. Correlation of the genetic properties of the various mutant haplotypes with the apparent position at which the crossover occurred has made it possible to map factors underlying the various properties. The most extensively studied batch of

mutant haplotypes is derived from the haplotype t<sup>6</sup> (Fig. 1), which belongs to the t<sup>0</sup> complementation group<sup>9-13</sup>. Less detailed results with mutants from other haplotypes suggest that they may be broadly similar to t<sup>6</sup> (refs 14-16).

Lethal t-haplotypes are usually maintained in balanced lethal stocks, using crosses of Ttf/t<sup>x</sup> × Ttf/t<sup>x</sup>, both T/T and t<sup>x</sup>/t<sup>x</sup> being lethal. In such stocks mutant t's are occasionally found which have lost the lethality and are viable when homozygous. In all cases this loss of lethality is accompanied by crossing over between T and tf. This suggested the existence of a lethal factor (the LS-factor), located near the locus of tf, and lost whenever the wild-type allele of this locus is lost (Fig. 1, for example, haplotypes t<sup>h2</sup> and t<sup>h3</sup>). This was confirmed by the finding in linkage tests of the complementary type of crossover (t<sup>h17</sup> and t<sup>h18</sup>, Fig. 1)<sup>9,11</sup>. Mutant t's of this kind are lethal either when homozygous or in compound with t<sup>6</sup>, but they do not produce taillessness when heterozygous with T; thus, T/t<sup>h17</sup> and T/t<sup>h18</sup> are short-tailed like T/+. This leads to the interpretation that the T-interaction effect is due to a factor located near the locus of brachyury. Further study of the two complementary types of mutants revealed that all the viable mutants were male fertile, and t<sup>h17</sup> and t<sup>h18</sup>, which retained the lethality, also retained the male sterility of t<sup>6</sup>. It thus seems that a factor for male sterility is close to that for lethality<sup>10</sup>. For simplicity, the two factors are shown as one in Fig. 1 (the LS-factor), but it is possible that they are separable.

The next factor to consider is segregation distortion in males. Mutant viable haplotypes are of two main kinds (Fig. 1): those with normal ratio (t<sup>h3</sup>) and those with a low transmission ratio from males (t<sup>h2</sup>). This suggests that a factor for low ratio might be located between T and tf. This concept was confirmed by the discovery of the mutant low<sup>17</sup>, later renamed t<sup>low</sup> (ref. 10), which arose by crossing over in a stock carrying t<sup>h17</sup>. It has the property of causing a low transmission (<50%) from males of the chromosome on which it lies, but it is viable when homozygous, and does not modify the effect of T. t<sup>low</sup> is thus regarded as a middle-piece of t-chromatin carrying the abnormal ratio factor, designated the A-factor, but not the T- or LS-factors. The finding (mentioned below) of further t<sup>low</sup>-type mutants in the present work confirms this interpretation. In males carrying t<sup>low</sup> and another t<sup>x</sup> with an abnormal transmission ratio, either high or low, the two haplotypes t<sup>low</sup> and t<sup>x</sup> are transmitted with equal frequencies. Thus, the first requirement for abnormal transmission is that the A-factor should be present and heterozygous. However, the A-factor alone gives a low ratio. The high ratio seen in naturally occurring haplotypes seems to depend on other parts of the t-chromatin. Thus, it has been suggested that the spaces between the T-, A- and LS-factors are occupied by abnormal t-chromatin of some kind, and that the high transmission ratio of natural t-haplotypes is due to the presence of the A-factor and interaction of this factor with all parts of the t-chromatin<sup>9,10</sup>.

A further property of natural haplotypes so far unexplained is suppression of recombination over the segment of chromosome 17 from T to H-2. Mutant haplotypes which arise by recombination between T and tf usually permit recombination in this region, although still with some suppression. Such weak suppression could be due to partial loss of the crossover-

suppressing property over the whole T-H-2 segment, or mutant haplotypes might still suppress crossing over strongly over their own (reduced) length and allow free recombination elsewhere. If the latter explanation were correct, double heterozygotes for two complementary and overlapping mutant haplotypes (for

**Fig. 1** Diagrammatic representation of the structure of the  $t^6$ -haplotype, of various mutant haplotypes derived from it, and of the corresponding normal segment of mouse chromosome 17. The centromere is depicted to the left in black. Some relevant known loci in the normal chromosome are brachyury, T; quaking, qk; hybrid sterility, Hst-1; fused, Fu; knobby, Kb; tufted, tf; and H-2. In the t-chromatin the postulated T-int-, A- and LS-factors are hatched and the intervening stretches of altered chromatin are stippled.

example,  $t^{h2}$  and  $t^{h17}$ , Fig. 1) should exhibit strong crossover suppression, even though each haplotype separately permits recombination. Conversely, in double heterozygotes for non-overlapping haplotypes (for example,  $t^{h2}$  and  $t^{h18}$ , Fig. 1), crossing over should occur freely in the segment of normal chromatin between the two stretches of t-chromatin. We have already presented evidence that in the double heterozygotes for  $t^{h18}$  and various viable T-end mutants, such as  $t^{h2}$ ,  $t^{h6}$  and  $t^{h11}$ , considerable crossing over in the relevant segment can occur<sup>9</sup>.

To test the overlapping haplotypes, animals heterozygous for  $t^{h2}$  and  $t^{h17}$  were bred. These particular haplotypes were known to overlap as both included the A-factor. The recombination between T and tf in these doubly heterozygous animals was then compared with the value in animals carrying  $t^{h17}$  only, and therefore having normal chromatin over part of the relevant distance (Table 1). In animals carrying only  $t^{h17}$ , the T-tf recombination is considerably enhanced (the normal value is about 8%), apparently an effect of the translocation T(1; 17)190Ca with which  $t^{h17}$  is inextricably associated. In the double heterozygotes  $t^{h2}/t^{h17}$ , however, recombination was strongly suppressed and was less than one-tenth of that in single  $t^{h17}$  heterozygotes ( $1.5 \pm 0.6$  compared with  $18.1 \pm 0.9\%$ , Table 1). The interpretation was that both  $t^{h2}$  and  $t^{h17}$  suppressed crossing over strongly over their own length, and thus, as the two haplotypes overlapped, recombination was strongly suppressed over the whole distance from T to tf.

## Other evidence

Hammerberg and Klein<sup>18</sup> showed that the crossover-suppressing effects of t-haplotypes extended beyond tf, approximately to the H-2 complex but little, if at all, beyond this. Thus, it is assumed that t-chromatin extends to H-2, but the absence of mutant haplotypes with breaks between tf and H-2 prevents a similar study of the basis of the crossover suppression in this segment. However, both  $t^{h17}$  and  $t^{h18}$  retain the H-2 haplotype of  $t^6$ , from which they were derived, even though they had been crossed to other stocks carrying other H-2 genes for many generations before their H-2 genotype was tested<sup>12</sup>. This is consistent with the idea that each t-haplotype suppresses crossing over for its own length, and that  $t^{h17}$  and  $t^{h18}$  extend distally as far as H-2, but it is not critical evidence.

There is little evidence concerning crossover suppression by mutants derived from natural haplotypes other than  $t^6$ . Bennett<sup>19</sup> bred animals doubly heterozygous for  $t^{38}$ , a viable mutant with low transmission ratio derived from  $t^0$  (ref. 15), and  $t^{low}$ . As  $t^{38}$  has a low ratio it must have included the A-factor (thus resembling  $t^{h2}$  in Fig. 1) and must have overlapped  $t^{low}$ . Bennett found no recombination between  $t^{38}$  and  $t^{low}$ , suggesting that  $t^{38}$ , like the  $t^6$ -mutants, suppresses crossing over throughout

**Fig. 2** a, Giemsa-stained chromosome 17 bivalents at pachytene. Examples of the synchronous and asynchronous synapsis observed in the large, pale 17B band in, left to right, +/+, T/+ and +/t<sup>6</sup> animals. Note also that in +/t<sup>6</sup> there is no detectable heterozygosity in the bivalent in length or staining intensity. b, Synaptonemal complexes and the diagrammatic interpretation of quadrivalents they form in T/+ and +/t<sup>w5</sup> T138 heterozygotes. Chromosome 17 and its translocated segments are shown as the continuous line, chromosome 9 and its segments as the broken line. Both quadrivalents show equivalent synapsis in the region of the 17B band (arrowed). The synaptonemal complexes were freed and fixed using the method described by Tres<sup>24</sup> but were then sedimented on to glass slides and stained with aqueous silver nitrate before viewing with the light microscope.

its own length. Pizarro and Dunn<sup>20</sup> showed that  $t^{w35}$ , a viable mutant derived from  $t^{w32}$ , decreased recombination in the T-tf interval and increased it in the tf-H-2 interval. This is consistent with the suggestion that  $t^{w35}$  suppressed crossing over strongly over its own length, leading to a compensatory increase in recombination in the adjacent segment.

**Table 1** The effect of overlapping t-haplotypes on T-tf recombination

Parents	Sex of heterozygote	Offspring				Total	Recombination (% $\pm$ s.e.)
		T+	Ttf	++	+tf		
T(t <sup>h17</sup> )/+tf $\times$ +tf/+tf	♀	399	79	84	352	914	17.8 $\pm$ 1.3
	♂	327	86	72	377	862	18.3 $\pm$ 1.3
T(t <sup>h17</sup> )/t <sup>h2</sup> tf $\times$ +tf/+tf	♀	70	—	2	81	153	1.3 $\pm$ 0.9
	♂	93	2	3	79	177	2.8 $\pm$ 1.2
		T++	T+tf	Tt <sup>h2</sup> +	Tt <sup>h2</sup> tf	Total	
+(t <sup>h17</sup> )/t <sup>h2</sup> tf $\times$ Ttf/+tf	♀	21	—	—	17	38	
	♂	44	—	—	41	85	
Combined data (t <sup>h17</sup> )/t <sup>h2</sup> tf	♀				RC	Total	
	♂				2	191	1.0 $\pm$ 0.7
					5	262	1.9 $\pm$ 0.8

Animals were classified for tail length within a few days (usually 1 day) of birth and for tufted, tf, at about 4 weeks. Any doubtful animals were kept and genetically tested. For the third group of crosses only the T-carrying offspring are shown as the remainder provide no linkage information. The seven recombinant animals in the crosses involving t<sup>h17</sup>/t<sup>h2</sup> were all genetically tested and shown to carry recombinant haplotypes. Both Ttf animals proved to be T(t<sup>low</sup>)tf/+tf. The 5++ animals all gave tailless offspring when crossed to T/+ (that is, they carried the T-int factor). Two permitted recombination between T and tf, and were shown to be due to chiasmata proximal to and distal to the overlap region; the remaining three are still being tested. RC, recombinant offspring.

Thus, the available evidence, though not conclusive, is entirely consistent with the suggestion that in any t-haplotype, whether natural or a derived mutant consisting of proximal, central or distal region, crossover suppression is co-extensive with the t-chromatin.

## Chiasma formation

In principle, crossover-suppression observed among the progeny may be due either to failure of chiasma formation or to normal chiasma formation with elimination of the products of crossing over.

Because at meiosis the chromosome 17 bivalent cannot be unequivocally identified, this question has been studied in t-haplotypes by marking the chromosome with translocations. In mouse translocation heterozygotes, if there is a chiasma in each arm of the multivalent then a ring is observed at meiotic metaphase I. If one arm lacks a chiasma then a chain configuration is formed, and if two arms lack chiasmata there may be either a chain-of-three plus univalent, or two unequal bivalents. Forejt<sup>21</sup> studied the configurations formed at first meiotic division in males heterozygous for T(9;17)138Ca, T(1;17)190Ca and T(8;17)43H. In each case animals carrying t<sup>12</sup> had a lower mean number of chiasmata in the translocated chromosomes than did their T/+ siblings. The reductions were 0.27, 0.25 and 0.45 chiasmata per multivalent in T138, T190 and T43, corresponding to map distances of 14, 13 and 23, respectively. Thus, they were approximately of the right order, as the recombination in T138 heterozygotes is reduced by about 9% when the haplotype t<sup>6</sup> is present<sup>22</sup>.

Because of the importance of this point, we have repeated Forejt's work, using T138 and three other t-haplotypes, t<sup>6</sup>, t<sup>w5</sup>

and t<sup>w32</sup>. Meiotic configurations in males heterozygous for T138Ca and a t-haplotype were compared with those in littermates or other close relatives heterozygous for T138 and T/+ (Table 2). In each case the number of chiasmata per multivalent was significantly lower in males carrying t<sup>6</sup>, t<sup>w5</sup> or t<sup>w32</sup> than in their T/+ relatives. For t<sup>6</sup> and t<sup>w5</sup> the reductions were 0.23 and 0.21 chiasmata per multivalent, respectively, quite close to the value found by Forejt for t<sup>12</sup>. With t<sup>w32</sup> the difference was greater, about 0.39 chiasmata, but as only two t<sup>w32</sup> males were studied, little importance can be attached to this point.

Our main conclusion is that, as a reduction in number of chiasmata in T138 multivalents is produced by four different t-haplotypes, t<sup>6</sup>, t<sup>12</sup>, t<sup>w5</sup> and t<sup>w32</sup>, then the crossover suppression caused by t is due to reduced chiasma formation, rather than elimination of products of chiasmata.

In other organisms factors which lead to chiasma suppression have been classified as asynaptic or desynaptic, according to whether synapsis fails or whether synapsis occurs normally but chiasmata do not form<sup>23</sup>. It would be valuable to know whether t-haplotypes should be considered as asynaptic or desynaptic. We attempted to study chromosome pairing in chromosome 17 of males with or without t by light microscopy of pachytene preparations. These studies revealed that the large pale Giemsa-staining band 17B pairs asynchronously even in normal (+/+ or T/+) animals and may be found unpaired when more proximal and distal bands are closely apposed (Fig. 2a). This is relevant as t-chromatin is thought to be located in this band (see below). However, there was no difference in pairing between +/t<sup>6</sup> or +/t<sup>w5</sup> and T/+ animals, either in these Giemsa-stained chromosomes or in synaptonemal complexes observed by light microscopy, using T138 as a marker of chromosome 17 (Fig. 2b). Thus, chiasma suppression in t-haplotypes is probably of

**Table 2** Multivalent configurations and chiasmata at first meiotic division in male mice heterozygous for T138Ca and various t-haplotypes

Haplotype	No. of males	RIV	No. of cells with configuration			Total	No. of chiasmata	Difference
			ChIV	ChIII+I	20II			
t <sup>w5</sup>	3	734	221	3	397	1,355	3.25	
Ttf	5	1,353	571	8	320	2,252	3.46	0.21
t <sup>w32</sup>	2	453	161	3	414	1,031	3.04	
Ttf	4	1,244	291	9	400	1,944	3.43	0.39
t <sup>6</sup>	7	2,176	570	22	1,189	3,957	3.24	
Ttf	5	1,860	452	16	503	2,831	3.47	0.23

Males were bred by crossing Ttf/t+  $\times$  T138/T138. Testis preparations were made by the method of Evans *et al.*<sup>34</sup> and stained with toluidine blue. Observations were made of cells in diakinesis-metaphase I using coded slides. RIV, ring of 4; ChIV, chain of 4; ChIII+I, chain of 3+univalent; 20II, no multivalent configuration.

the desynaptic type, but further work, probably involving electron microscopy, is needed to confirm this point.

The chiasma suppression of *t*-haplotypes is typically studied in heterozygotes, having normal chromatin on the homologous chromosome. It would be valuable to know whether chiasmata are also suppressed when *t*-chromatin is present on both homologues. Does the abnormality involve mutual recognition of *t*-chromatin and normal chromatin, or is the low chiasma-forming property of *t*-chromatin autonomous?

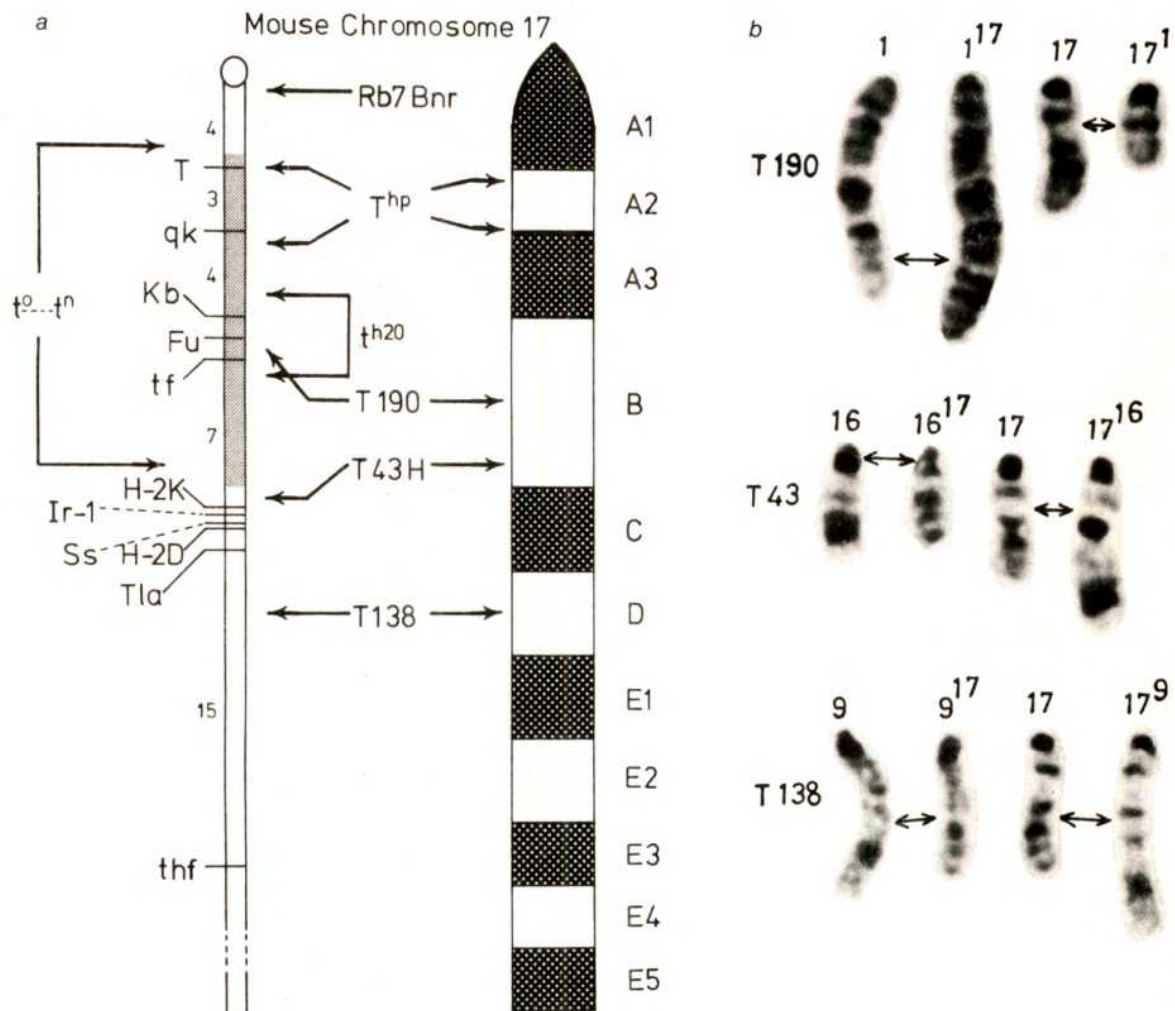

Crosses intended to test this point are in progress but have been inconclusive. Similarly, the crossover haplotypes derived from the  $t^{h2}/t^{h17}$  heterozygotes are being studied to determine whether any have resulted from chiasmata in the overlap region. To date, two  $t^{low}$  type mutants have been found (which give no information on chiasma position) and one each of mutants resulting from chiasmata proximal to and distal to the overlap region. It seems likely that chiasmata are suppressed at least to some extent, when *t*-chromatin is homozygous as well as when it is heterozygous, but further work is needed on this point.

### Location and extent of altered chromatin

Genetically, the crossover-suppressing effect of *t*-haplotypes extends from the *T* to *H*-2 loci, but apparently not far beyond

*H*-2 (ref. 18). There is little evidence about the effect proximal to the *T*-locus.

Cytogenetically, part (and perhaps all) of the *t*-chromatin lies in band 17B, the large band in chromosome 17, which stains lightly with Giemsa. The evidence for this comes from the relative location of translocation breaks and genetic markers (Fig. 3a). Translocations *T*(1; 17)190Ca and *T*(16; 17)43H have breaks in band 17B (refs 25, 26), and *T*(9; 17)138Ca in band 17D (ref. 25) (Fig. 3b). Genetically, the *T*138 break is 3cM distal to *H*-2 (ref. 27) and that in *T*43H is very close to *H*-2K (ref. 28). Thus, it seems probable that the *H*-2 complex, and hence the distal end of *t*-chromatin, lies near the distal end of band 17B. The locus of *tf* (near the centre of the *t*-chromatin) apparently lies distal to the *T*190 break, and hence also in 17B (ref. 29). The position of the brachyury locus is less certain. Bennett<sup>1</sup> reported that the brachyury allele, *T*<sup>hp</sup>, which involves a deletion extending from *T* to *qk*, was cytogenetically detectable as a shortening of the A2 band. However, we have been unable to confirm this. In preparations made from 12-day embryos, some *T*<sup>hp</sup>/*t*<sup>h2</sup> and others *+*/*t*<sup>h2</sup>, no consistent differences between the pairs of chromosome 17 were detected (Fig. 4). Hence, it is not clear whether the *T* locus lies in band 17A2, or whether it too lies in 17B. Thus, the stretch of altered chromatin in *t*-haplotypes probably occupies the whole of band 17B and may extend proximally into the 17A bands.

**Fig. 3** *a*, Genetic (left) and cytogenetic (right) maps of mouse chromosome 17. In the genetic map the segment thought to be occupied by *t*-haplotypes is shaded. The approximate positions of the breakpoints in *T*190Ca, *T*43H, and *T*138Ca are shown by arrows. The genetic positions were determined by pedigree analysis; the evidence for the cytogenetic positions is shown in *b*. Gene symbols as in Fig. 1 and also *Ir*-1, immune response-1; *Ss*, serum serological (factor C4 of complement); *Tla*, thymus leukaemia antigen; *thf*, thin fur. *b*, G-banded normal and translocated chromosomes showing breakpoints (arrowed) in *T*190Ca, *T*43H and *T*138Ca heterozygotes.

## Nature of the genetic changes

Although the exact mechanism remains unknown, it seems that t-chromatin alters the function of the chromosome at meiosis in such a way that chiasma formation is reduced. Moreover, as previously known, chromosome function in development is altered by t-chromatin, leading to embryonic lethality, modification of tail length and effects on spermatogenesis. In considering the type of change in the DNA which could produce such effects, it seems that major structural changes, such as inversions, are ruled out, as are long-range position effects acting from only one or two points. Such position effects could not explain the way in which effects on recombination change with length of haplotype, nor the fact that not only proximal and distal ends but also central fragments ( $t^{\text{low}}$ -mutants) can retain t-properties. It seems that some change repeated along the altered stretch of DNA in band 17B must be involved. DNA of higher organisms is thought to have five levels of organisation<sup>30</sup>: (1) unique sequences, including structural genes for proteins; (2) repeated genes coding for some types of RNA and protein for which multiple coding sequences are required; (3) moderately

**Fig. 4** Above, three G-banded homologous pairs of chromosome 17 from  $+/t^{\text{h}2}$  embryos and below, three from  $T^{\text{hp}}/t^{\text{h}2}$  embryos, showing no detectable heterozygosity in length or staining of the pale A2 band (arrowed).

repetitive sequences interspersed with the coding DNA (iDNA); (4) highly repetitive DNA, other than satellite DNA; (5) satellite DNA having highly repeated sequences and located in large blocks of chromatin.

We postulate that in t-chromatin it is the moderately repetitive DNA, that is, level (3) of organisation, in the chromosomal segment occupied by each haplotype, that is altered. The structural sequences in this segment seem to be present and normal. The evidence for this is that there are various known loci in the region occupied by t-haplotypes, such as the loci of qk, Kb and tf, for which t-chromatin seems to behave in a similar way to wild-type. Thus,  $t/qk$ ,  $t/Kb$ , and  $t/tf$  phenotypically resemble  $+/qk$ ,  $+/Kb$ , and  $+/tf$ , respectively. Therefore, one must assume that t-chromatin includes normal structural sequences for these loci. Conversely, a change in the iDNA could account for the observed phenomena. Such sequences are believed to be involved in the 'fine-tuning' of gene expression<sup>30</sup>, and in meiotic crossing over<sup>31</sup>. We postulate that t-chromatin differs from normal in such a way that chiasma formation is impaired, and in development the function of different structural loci is or is not materially altered, according to their dependence on the particular change in 'tuning', which might, for instance, involve an alteration in timing or rate of transcription. Many of the effects might be quantitative, but if a processing gene<sup>32</sup> was affected

then polypeptide structure might be altered. The lethality would result from one or more profoundly affected structural loci, the T-int effect from a slight effect on the T locus, whereas loci such as qk, Kb and tf, are not detectably affected.

Because the relevant sequences are repeated, any change in them need not necessarily be an alteration in the sequence, but might instead be an altered number of repeats, or a combination of these factors. Each naturally occurring t-haplotype, such as  $t^0$ ,  $t^{\text{w}1}$ , and  $t^{\text{w}5}$  must be considered as potentially having its own particular type of altered iDNA. Hence, the T-int-, A- and LS-factors would potentially exist in allelic forms, according to the haplotype from which they were derived.

The means by which naturally occurring t-haplotypes arise from wild type is problematic. For repetitive sequences some mechanism, not yet understood, may exist by which a change can occur throughout a chromosome segment, such as mouse chromosome 17B, in a single event. On the other hand, it is not certain that t-haplotypes do arise in a single event. In the laboratory, short stretches of t-chromatin found in mutant haplotypes are indefinitely stable. Therefore, it is possible that in the wild, short stretches arise and become elongated by unequal crossing over until they reach a length at which they have a high transmission ratio, by which they are then maintained in the wild population. The high transmission, combined with deleterious effects (lethality and sterility), gives the impression of a 'parasitic gene' (ref. 33), and this in turn raises the possibility that incorporated viral genomes may in some way be involved in t-haplotypes. However, any explanation along these lines would be purely speculative.

Finally, if t-haplotypes are viewed as alterations in iDNA they acquire a new significance in studies of mouse genetics. Such DNA forms a significant part of the genome and if, as postulated, it affects gene expression, it would be expected to have important effects on the phenotype. Little work has so far been done on this question: t-haplotypes may provide a suitable system for future work.

We thank M. D. Burtenshaw and B. B. Brown for assistance in scoring meiotic configurations in T138Ca heterozygotes, and G. Wilkins for photography.

# Expression in *Escherichia coli* of hepatitis B virus DNA sequences cloned in plasmid pBR322

*Fragments of hepatitis B virus DNA isolated from Dane particles have been inserted into the Escherichia coli plasmid pBR322 and cloned. Cells carrying the hybrid plasmid synthesise antigenic material that reacts specifically with antisera to hepatitis B viral antigens.*

INFECTION with hepatitis B virus (HBV) is widespread in man. Between 3 and 15% of healthy blood donors in Western Europe and the US show serological evidence of past infection and about 0.1% are chronic carriers of the virus. In many African and Asian countries the prevalence is much higher and the majority of the adult population have been infected, while 5–10% of the population are chronically infected<sup>1</sup>. Most infections are subclinical and are followed by apparently complete recovery with the development of virus-specific antibody. However, a significant proportion of infections (probably 1–5%) may produce chronic sequelae including persistent infection, chronic hepatitis of various types, cirrhosis and possibly primary liver cancer.

Plasma from some blood donors and patients infected with HBV contains 42-nm spherical particles (Dane particles)<sup>2</sup> which have serological and biochemical properties, suggesting that they are the infective virions of hepatitis B. These have an outer envelope containing the hepatitis B surface antigen (HBsAg) and an inner core (diameter 27 nm) bearing a second unrelated antigen, the hepatitis B core antigen (HBcAg). Within the core is a double-stranded circular DNA molecule of molecular weight  $\sim 2 \times 10^6$  which has a large variable gap in one strand, and an endogenous DNA-dependent DNA polymerase activity that can fill in this gap in *in vitro* reactions<sup>3</sup>. There is some evidence that the total virus genome length may be around one-third greater than the  $2 \times 10^6$  daltons found in single molecules in which case productive infection of a cell may require simultaneous infection by at least two genetically different particles<sup>3</sup>. A third antigen, the hepatitis B e antigen (HBeAg), which is probably also virus-coded, is found free in the plasma of some infected individuals and possibly also in association with Dane particles. Passively or actively acquired antibody to HBsAg (anti-HBs) confers some immunity to subsequent HBV challenge, and prototype vaccines composed of purified inactivated HBsAg prepared from the plasma of infected carriers are being evaluated<sup>4</sup>. However, the virus cannot be grown in tissue culture and normally infects only man and apes. This means that

molecular studies of the virus and its genome have been based on the limited amounts of material obtainable from the plasma of infected individuals. Such studies could be advanced considerably by insertion of HBV DNA into a bacterial plasmid or phage to allow its production in quantity from cloned, purified single molecules. Such clones would also be useful for studies of the expression of HBV gene products in bacterial cells, and for large-scale production of HBV DNA and viral antigens for diagnostic purposes and, possibly, vaccine production.

## Restriction of HBV DNA

The published information on digestion products of HBV DNA (Dane particle DNA) with restriction endonucleases<sup>5,6</sup> is limited and so additional analyses of this type were carried out before attempting cloning experiments. The amount of HBV DNA available was limited (about 90 ng from 5 ml of plasma), so the DNA was first labelled with <sup>32</sup>P in the endogenous DNA polymerase reaction<sup>3</sup>. DNA from bacteriophage  $\lambda$  was then added as a carrier to titrate the restriction enzyme and to provide reference fragments of known size. The digests were analysed by electrophoresis in agarose gels and the results of some of these experiments are shown in Fig. 1.

The heterogeneity of the undigested labelled HBV DNA (tracks *b* and *e*) precluded a detailed analysis of the restriction digests. The multiple bands of rather similar size could be due in part to the presence of linear and circular forms of otherwise similar molecules, in part to differing degrees of repair synthesis, although repeated DNA preparations from the same plasma sample gave reproducible patterns; the heterogeneity could also represent a true molecular dispersity from a mixed population of virions. HBV DNA preparations from several individual donors were all heterogeneous and differed slightly from each other (an example is included in Fig. 1; tracks *a*, *b* and *c* compared with *d*, *e* and *f*) both before and after digestion with various restriction enzymes. Heterogeneity has also been observed by Landers *et al.*<sup>6</sup> in the products of the endogenous polymerase reaction which comprised two principal radioactive components representing linear and circular molecules with additional minor components due to incomplete repair. Examination of the HBV DNA (Fig. 1, tracks *b* and *e*) by electron microscopy showed that the population contained circular molecules of MW  $\sim 2 \times 10^6$  and linear molecules ranging from 0.5 to  $10 \times 10^6$ . The linear molecules represented about three times the concentration of circular molecules and only a few of them had a MW around  $2 \times 10^6$ , the majority being between 0.5 and  $1 \times 10^6$ . The heterogeneity observed on electrophoresis was, therefore, not due to circular and linear forms of similar length and few, if any, of the linear molecules were labelled in the polymerase reactions.

**Fig. 1** Autoradiographs of restriction enzyme digests of HBV DNA after electrophoresis in agarose gels. Examples of HBV DNA isolated from the plasma of two blood donors are shown, the samples in tracks *a*, *b* and *c* from one donor being directly comparable with those in tracks *d*, *e* and *f* from the other; the sample used for the digests in tracks *d*, *e* and *f* was also used for all the other digests shown, and also for the preparative experiments for cloning. In addition to the autoradiographs, the figure includes examples, indicated by primed letters, of the gels stained with ethidium bromide to reveal fragments of the  $\lambda^+$  DNA included with the HBV DNA in the restriction reactions. HBV DNA was prepared from Dane particles isolated by two cycles of ultracentrifugation from clarified plasma obtained from individual HBsAg-positive blood donors essentially as described by Landers *et al.*<sup>6</sup>. The single-strand gaps in the DNA molecules were repaired and the DNA radioactively labelled in reactions with the endogenous DNA polymerase in which  $^3\text{H}$ -dCTP and  $^3\text{H}$ -dTTP (22 and 30 mCi  $\mu\text{mol}^{-1}$ , respectively; Radiochemical Centre Amersham) or  $^{32}\text{P}$ -dGTP (300 mCi  $\mu\text{mol}^{-1}$ ) were included<sup>6</sup>. The released core particles were further purified by sedimentation through 30% w/v sucrose solution and DNA was isolated by treatment with proteinase K (Boehringer-Mannheim; 2 mg  $\text{ml}^{-1}$  in 0.6% SDS) followed by phenol extraction and dialysis. Restriction enzyme digests (37 °C, 1.5 h) were carried out in 10 mM Tris-HCl, pH 7.5, 10 mM  $\text{MgCl}_2$ , 10 mM 2-mercaptoethanol, 40 mM NaCl after addition of phage  $\lambda$  DNA (0.5–1  $\mu\text{g}$  per reaction) and the reactions were stopped by heating at 70 °C for 5 min. The samples were then applied to 1% w/v agarose gels<sup>23</sup> in 0.04 M Tris-acetate, pH 8.2 for electrophoresis (35 mA, 8 h). Gels were stained with ethidium bromide and photographed under UV light<sup>24</sup> and then either placed in alkali to denature DNA fragments for transfer to cellulose nitrate membrane filters<sup>13</sup> or dried on Whatman 3MM paper for autoradiography. The MW of the fragments of HBV DNA was estimated from their electrophoretic mobility<sup>24</sup> with reference to fragments of  $\lambda^+$  DNA in digests with *R.EcoRI* and *R.HindIII* included in the same gel<sup>25</sup>. These results are included in Fig. 2 which gives a provisional map of some of the restriction targets relative to each other.

Digestion of HBV DNA with *R.EcoRI* or *R.BglII* changed the pattern of the major bands only slightly (Fig. 1 tracks *c*, *f* and *g*) whereas digestion of the DNA with these two enzymes together (track *h*) gave a radioactive fragment, MW  $0.75 \times 10^6$  as the principal component, with little of the original DNA remaining. This is consistent with the introduction of a single break in circular molecules by either enzyme alone to give intact linear molecules; when the two enzymes acted together two fragments were formed, the smaller containing the entire labelled region. On digestion with *R.KpnI* (track *i*) almost the whole group of bands was displaced down the gel corresponding with the loss from each of a fragment of MW  $\sim 0.4 \times 10^6$  but no corresponding radioactive fragment was found. This suggests that HBV DNA may contain at least two targets for *R.KpnI* located outside the region repaired in the reaction with DNA polymerase and spanning a sequence common to all the molecules. The alternative explanation requiring cleavage of circular molecules at a single target to give linear molecules is less likely in view of the behaviour observed in the *R.EcoRI* and *R.BglII* digests. *R.HaeIII* furnished a spectrum of fragments with a range of sizes (track *r*) in a pattern broadly similar to that published<sup>5,6</sup>. Digestion of HBV DNA with *R.AvaI* and with

*R.BamHI* gave several radioactive fragments (tracks *j* and *g*); a major product of the *R.AvaI* digest had a MW of  $0.88 \times 10^6$ , while radioactive fragments of  $1.2 \times 10^6$  and  $1.8 \times 10^6$  occurred in the *R.BamHI* digests; in other digests with *R.BamHI* smaller fragments were also observed. These results, together with the principal radioactive products found in various digests with pairs of restriction enzymes (for example, *R.EcoRI* and *R.AvaI*, track *a* or *d*) are summarised in Fig. 2. Within the constraints imposed by the dispersity of the HBV DNA preparations used, they provided the approximation of relative positions of restriction targets as shown.

The results imply that, in most molecules, the single-stranded gap repaired by the endogenous DNA polymerase lies within a relatively constant region of the DNA sequence; Landers *et al.*<sup>6</sup> similarly concluded, from an analysis of *R.HaeIII* digests after different polymerase reaction times, that DNA repair took place largely within the same one-third to one-half of the total DNA sequence, although initiation of DNA repair could occur at variable sites within this region.

Digests of HBV DNA with *R.EcoRI* or *R.BglII* offer the possibility of cloning the entire HBV genome, while major fragments might be cloned from digests with *R.BamHI*, *R.KpnI*

or *R.AvaI*, or from various double digests. For structural studies of the HBV genome it is desirable to clone the entire DNA molecule, but clones covering a range of fragments could well be more useful for attempts to demonstrate the expression of HBV sequences in *E. coli*. Micromethods based on radioimmunoassay can be applied to individual bacterial colonies or phage plaques for the detection of specific polypeptides<sup>7</sup>. As many eukaryotic genes will not be expressed in prokaryotic cells it appeared desirable to insert HBV DNA fragments within a prokaryotic gene so as to produce a fused polypeptide; for this purpose the *R.Pst* target in the *E. coli* plasmid pBR322 has been used successfully<sup>8</sup>.

### Cloning of HBV DNA fragments in pBR322

HBV DNA isolated from Dane particles from a single HBsAg positive, HBeAg positive donor (serotype *adyw*) was labelled to a low specific radioactivity with <sup>3</sup>H in a repair reaction with the endogenous polymerase in order to facilitate its handling. This preparation was then variously digested with *R.EcoRI*, *R.BamHI*, *R.BglII*, *R.KpnI* and *R.AvaI*. Portions of the *R.EcoRI* and *R.BamHI* digests were used for insertion at the respective sites of appropriately restricted pBR322 DNA by annealing and ligation with T4 DNA ligase. The fragments from the other restriction enzyme digests and the remainder of the *R.EcoRI* and *R.Bam* digests were treated with polynucleotide terminal transferase for addition of 3' oligo (dC) sequences<sup>9</sup>. These fragments were annealed to pBR322 DNA to which oligo (dG) sequences had been attached after cleavage with *R.Pst*. The DNA preparations were then used to transform competent cultures of *E. coli* HB101 and transformants were screened for the acquisition of HBV sequences on the following basis. Cells transformed with recombinants made using the *R.Pst* site in pBR322 retained their resistance to tetracycline, but became sensitive to ampicillin. Cells transformed with recombinants made using the *R.BamHI* site in pBR322 became sensitive to tetracycline, but retained their resistance to ampicillin, while cells transformed with DNA cloned using the *R.EcoRI* site remained resistant to both antibiotics<sup>10</sup> and were detected by colony hybridisation<sup>11</sup> with <sup>32</sup>P-labelled DNA from Dane particles. The presence of HBV DNA sequences in colonies where antibiotic resistance and sensitivities indicated the insertion of additional DNA into the plasmid was confirmed by colony hybridisation.

### Characterisation of pBR322-HBV hybrids

Plasmid DNA isolated from cell cultures that had been treated with chloramphenicol to amplify plasmid production<sup>12</sup> was analysed by gel electrophoresis before and after digestion with restriction endonucleases.

DNA fragments from several of the gels were transferred to cellulose nitrate filters for hybridisation<sup>13</sup> with HBV DNA labelled with <sup>32</sup>P by the endogenous polymerase reaction. Examples of these results are shown in Fig. 3 and some of the characteristics of the cloned segments are given in Table 1. The hybridisation observed with appropriate fragments does not establish conclusively that the cloned sequences were HBV-specific, for the cloned DNA and <sup>32</sup>P-labelled probe had been prepared from the same plasma sample. Thus contaminating non-viral DNA fragments that had been cloned inadvertently would also have been detected if the same non-viral DNA sequence was labelled by the endogenous polymerase; however, in other experiments such <sup>32</sup>P-labelled probes hybridised with DNA from HBV-infected liver tissue, but not with DNA from normal human liver. Furthermore, preparations of <sup>32</sup>P-labelled DNA made from Dane particles purified from four different blood donors gave the same patterns when hybridised against restricted DNA fragments from the recombinant plasmids, thus strengthening the view that the cloned sequences were in fact HBV DNA.

The results presented in Fig. 3 are examples taken from the large number of recombinant colonies obtained from the transformation experiments and relate to colonies described below.

Fig. 2 The size and approximate relative order in the HBV genome of some of the major fragments in various restriction enzyme digests (Fig. 1) of HBV DNA. The site for *R.EcoRI* is taken arbitrarily as a reference point for the circular map. The shaded area indicates the region labelled with <sup>32</sup>P in the endogenous repair reaction.

### Expression of HBV sequences

A population of the colonies carrying putative recombinant plasmids, selected on the basis of drug resistance and sensitivity characteristics, was screened for the production of HBV antigens. Three test systems were used in the solid phase method of radioimmunoassay described by Broome and Gilbert<sup>7</sup> which uses polyvinyl disks coated with IgG from specific antisera. These disks are placed in contact with cells producing antigen which binds to the IgG surface. When subsequently incubated with <sup>125</sup>I-labelled IgG from the same antiserum, the bound antigen retains the label and can be detected readily by autoradiography. The sera used were anti-HBs (human and hyperimmune animal sera), anti-HBc (human sera containing HBsAg and HBeAg and selected on the basis of a high anti-HBc titre) and anti-HBe and anti-HBe together (human sera containing HBsAg and high levels of anti-HBc and anti-HBe).

Clear positive results were obtained in the two test systems containing anti-HBc. Of some 350 colonies tested, 13 gave intense spots on autoradiography with the anti-HBc + anti-HBe antibodies (Fig. 4a). Most of these colonies remained strongly positive when re-tested in both the anti-HBc and anti-HBc + anti-HBe assay systems (Fig. 4b). None of the clones giving a negative response in the initial screening was subsequently positive, but some clones that were positive initially gave a negative result after subculturing, which probably reflects instability of some of the hybrid plasmids. All of the clones that were positive in the anti-HBc + anti-HBe system were positive when tested with anti-HBc alone, implying that none was producing detectable levels of HBeAg. If lysis of the bacterial colonies with phage  $\lambda$  before radioimmunoassay was omitted, only a very faint outline of the positive colonies was discernible (Fig. 4c). This is consistent with the presence of the antigen as a periplasmic polypeptide fused to the major part of  $\beta$ -lactamase (penicillinase) as anticipated. The sensitivity of this assay was shown to be comparable with that attainable with the same reagents in a solid phase microtitre well assay<sup>14</sup> by titration of 10  $\mu$ l samples (diluted progressively from 1 in 400) of semi-purified HBcAg from human liver<sup>15</sup>.

The immunological specificity of the reactions was confirmed by the following observations. Replicate assays with different anti-HBc sera identified the same positively reacting clones. The positive reactions in the HBcAg assay were abolished if the polyvinyl disks were coated with normal human IgG instead of specific anti-HBc IgG, or if the normal human serum used as diluent for the <sup>125</sup>I-labelled antibody was replaced by anti-HBc-positive serum from a different donor (by competition with excess unlabelled anti-HBc), or if <sup>125</sup>I-anti-HBs replaced <sup>125</sup>I-anti-HBc in the assay with the anti-HBc coated disks. Finally,

**Fig. 3** Electrophoretic separation in agarose gels of restriction enzyme digests of recombinant plasmids comprising pBR322 and HBV DNA sequences. The examples shown are of plasmids (Table 1) that elicit production of antigenic material that reacts specifically with antibodies to HBcAg (Fig. 4). The left-hand panels show DNA fragments revealed by staining with ethidium bromide and photography under UV light. After photography, gels were soaked in alkali for denaturation of the DNA fragments which were then transferred to cellulose nitrate membrane filters<sup>13</sup> for hybridisation with <sup>32</sup>P-labelled HBV DNA and autoradiography; the right hand panels show the corresponding radioautographs. HBV DNA (~0.5 µg) labelled with <sup>3</sup>H was prepared from 40 ml clarified blood plasma from a donor with a high titre of HBsAg, serotype *adw* as described in the legend to Fig. 1 and ref. 6. In one experiment 0.5 µg *E. coli* DNA was added as a carrier, but in a second the carrier was omitted. The DNA was divided into six portions for various restriction enzyme digests. Portions of *R. EcoRI* and *R. BamHI* digests were incubated with pBR322 digested with the same enzyme in reactions with T4DNA ligase<sup>26</sup> (1 U ml<sup>-1</sup>, 10 °C for 3 h followed by storage at 0 °C) in 66 mM Tris-HCl pH 7.2, 10 mM MgCl<sub>2</sub>, 40 mM NaCl, 0.2 mM EDTA, 0.1 mM ATP, 10 mM 2-mercaptoethanol. The remainder of the *R. EcoRI* and *R. BamHI* digests as well as *R. KpnI* and *R. BglII* digests were used in terminal transferase reactions, but with the exception of the *R. KpnI* digest the samples were first incubated with phage λ exonuclease (1.5 h at 0 °C in 50 mM Na glycinate, pH 9.5, 5 mM MgCl<sub>2</sub>, 50 µg ml<sup>-1</sup> bovine serum albumin (BSA) followed by phenol extraction and recovery of the DNA by ethanol precipitation) to remove the 5' single-stranded projections left by the restriction enzymes. Poly(dC) sequences were attached to the 3' termini by incubation with polynucleotide terminal transferase<sup>9</sup> (250 U ml<sup>-1</sup> for 10–20 min at 27 °C) in 15 µl 100 mM potassium cacodylate, pH 7.0, 1 mM CoCl<sub>2</sub>, 1 mM dCTP, 50 µg ml<sup>-1</sup> BSA, and the reactions stopped by addition of excess EDTA. An approximately molar equivalent of pBR322 DNA digested with *R. Pst* and incubated in similar reactions with dGTP instead of dCTP (from Dr J. van den Berg) was then added and the samples diluted to 50 µl for annealing in 50 mM Tris-HCl, pH 7.5, 100 mM NaCl, 5 mM EDTA, heated to 60 °C and gradually cooled to room temperature over a period of about 5 h. Aliquots of the solutions (10 µl) were then incubated with competent cultures (0.1 µl) of *E. coli* HB101 prepared as described by Lederberg and Cohen<sup>27</sup> and incubated overnight at 37 °C on L-agar plates containing tetracycline (20 µg ml<sup>-1</sup>) or ampicillin (50 µg ml<sup>-1</sup>). Colonies were subcultured on to Millipore filters supported on appropriate agar plates to test their resistance or sensitivity to the two antibiotics and for colony hybridisation<sup>11</sup> with <sup>32</sup>P-labelled HBV DNA from Dane particles. Colonies giving positive hybridisation reactions were grown in liquid culture and then shaken overnight at 37 °C after addition of chloramphenicol (170 µg ml<sup>-1</sup>) to amplify the number of plasmids within the cells which were then collected by centrifugation and treated with lysozyme and EDTA<sup>12</sup>. The resulting spheroplasts were lysed with Triton X-100 and the plasmid recovered by equilibrium centrifugation in CsCl solution (0.95 g per ml lysate) containing ethidium bromide (200 µg ml<sup>-1</sup>). The plasmid bands were collected, extracted with propan-1-ol saturated with aqueous CsCl, dialysed, and samples digested with restriction endonucleases as described in the legend to Fig. 1. The results shown are from the following hybrid plasmids: pHBV-66 in tracks a, b, c and d in which a is the undigested plasmid and b, c and d are digests with *R. Pst*, *R. KpnI* and *R. BamHI*, respectively; pHBV-110 in tracks e, f, g and h, in which e is the undigested plasmid and f, g and h are digests with *R. Pst*, *R. BamHI* and *R. BamHI* + *R. EcoRI*, respectively; pHBV-139 in tracks j, k, l, m and n, in which j is the undigested plasmid and k, l, m and n are digests with *R. Pst*, *R. BamI*, *R. EcoRI*, and *R. BamHI* + *R. EcoRI*, respectively. Tracks i and p show reference digests of λ<sup>+</sup> DNA with *R. EcoRI* + *R. HindIII*<sup>25</sup> which also contained <sup>32</sup>P-labelled undigested DNA from Dane particles. The primed letters identify the samples on the autoradiograph, made on Kodak X-omat H X-ray film with an intensifying screen, of the cellulose nitrate filters after hybridisation with HBV DNA.

absorption of the radioactive anti-HBc with semipurified HBcAg<sup>15</sup>, by overnight incubation at 4 °C followed by centrifugation to remove the excess antigen, abolished the positive result in the radioimmunoassay. Thus the detection of an as yet unidentified HBV-specific antigen by interaction with its specific antibody present in the sera of HBV-infected individuals remains a formal possibility, but it is unlikely, and the results are wholly consistent with the observed activity being that of HBcAg. The HBcAg polypeptide detected in the colonies, however, is unlikely to be identical with that occurring naturally for the cloning experiment was such as to produce polypeptides linked to β-lactamase<sup>8</sup>. However, it has not been established that this is the case and it remains possible that translation of β-lactamase sequences could be terminated and followed by reinitiation, but against this is the occurrence of clones that do not exhibit HBcAg activity, but which contain HBV DNA fragments similar to those that do. The point will be clarified by DNA sequence determination, which is in progress. All of the 13 HBcAg-positive clones had been made using the *R. Pst* site in pBR322, five with fragments from *R. BamHI* digests of HBV DNA and eight from *R. KpnI* digests. Not all of the plasmids have been isolated for analysis, but the three illustrated in Fig. 3 were all from cells giving positive reactions for HBcAg. The smallest fragment of HBV DNA in these plasmids (Table 1) was about  $0.95 \times 10^6$  daltons, but others with an HBV fragment

about half this size also gave positive reactions for HBcAg; values reported<sup>3</sup> for the MW of the naturally occurring HBcAg range from 17,000 to 80,000.

In an equivalent assay for HBsAg, similar, but faint positive reactions were obtained with four clones which are being analysed further. One might expect detection of expression of serological activity to be more difficult with HBsAg than with HBcAg as its protein moiety is markedly hydrophobic and hence

**Fig. 4** Autoradiographs showing the detection by radioimmunoassay of bacterial colonies expressing HBcAg. a, Four HBcAg-positive colonies amongst 52 colonies examined on one plate. b, The result obtained when initially positively reacting colonies, together with a random selection of colonies giving a negative reaction, were subcultured from stock plates and re-tested. c, A duplicate of b in which lysis of the colonies with phage λ before radioimmunoassay was omitted. Colonies of the bacteria were grown at 37 °C overnight on Millipore filters supported on nutrient plates containing tetracycline (to maintain selection for the plasmid). The cells were lysed by imprinting the filters for a few minutes on a lawn of bacteria confluent lysed with a virulent derivative of phage λ and then incubating further for several hours at 37 °C. Polyvinyl disks coated with anti-HBc + anti-HBe specific human IgG (60 µg ml<sup>-1</sup>) were placed face down on the colonies, which had obviously lysed, and incubated at 4 °C for 3–4 h. The disks were then removed and washed thoroughly and vigorously to remove the considerable quantity of adherent viscous bacterial debris. Finally the disks were incubated overnight at 4 °C with homologous <sup>125</sup>I-labelled IgG (10<sup>5</sup> c.p.s. per µg,  $2 \times 10^4$  c.p.s. per ml), washed thoroughly and autoradiographed on Kodak Blue X-ray film exposed for 2 d with an intensifying screen.

**Table 1** Some properties of the plasmids shown in Fig. 3

Hybrid plasmid	MW of fragment excised by <i>R. Pst</i> × 10 <sup>-6</sup>	Targets for restriction enzymes within the HBV sequences		
		<i>R. EcoRI</i>	<i>R. BamHI</i>	<i>R. Aval</i>
pHBV-66	1.2	—	+	+
pHBV-110	0.95	—	+	+
pHBV-139	1.16	—	+	+

In all the plasmids, the site for *R. BamHI* within the HBV sequence is located about  $0.7 \times 10^6$  daltons from the *R. Pst* site near the *R. EcoRI* site.

tends to remain associated with lipid<sup>16</sup>, and some experiments (but not others) suggest that carbohydrate residues on HBsAg glycoprotein may be required for full serological activity<sup>17,18</sup>.

## Conclusions and further implications

A large number of hybrid DNA molecules comprising pBR322 and various fragments of the HBV genome have been cloned and propagated in *E. coli*. It thus becomes possible to produce HBV DNA in the quantities required for detailed structural and sequence analysis and location of the various coding sequences in the viral genome. Such analysis with DNA from several independent isolates and clones will explain the basis of the heterogeneity found in DNA from Dane particles. The DNA will also be useful for further genetic manipulation related to studies of expression and as a source of a highly radioactively labelled probe for hybridisation experiments for both diagnostic purposes and fundamental studies.

When inserted within a normal coding sequence of the *E. coli* plasmid the DNA from hepatitis B virus, which normally infects only man and apes, can be expressed to give serologically active translation products. This suggests that at least the region of the HBV genome coding for the amino acid sequence necessary for serological activity probably does not contain inserted sequences, or 'introns', which have now been found in a number of eukaryotic and viral genes<sup>19-22</sup>, for it is widely believed, although not proved, that *E. coli* cannot process transcripts of these sequences. None of the hybrid plasmids so far examined contains a target for *R. EcoRI* within the HBV sequences. It was thus possible to insert the entire plasmid into a derivative of bacteriophage  $\lambda$  using this restriction site and plaques of the recombinant phage gave positive reactions in the disk radioimmunoassay (results not shown). The HBV sequences may well prove more stable when propagated within the phage genome, especially as a lysogen, and appropriate exploitation of the phage regulatory systems should permit significantly increased yields of the antigens from *E. coli*, raising the possibility of large scale antigen production for diagnostic purposes and development of vaccines. The insertion of HBV DNA into a phage  $\lambda$  derivative has been described very recently by Fritsch *et al.*<sup>28</sup>.

We thank Professor B. P. Marmion, Dr R. J. C. Harris and many of the staff at MRE, Porton, for their help, Glynis Leadbetter for radioimmunoassay reagents, Archie Barr and Anthony Keen for HBsAg-positive plasma, Johan van den Berg and Professor Charles Weissmann for reagents and help with terminal transferase reactions, Eric Gowans and Pamela Beattie for electron microscopy, Carol White and Eva Zehelein for technical assistance. This work was assisted in part by a grant from the Scottish Home and Health Department and was supported partly by Biogen S.A. Cloning experiments were performed in CIV conditions as recommended by GMAG; work on DNA from Dane particles was done in a CI laboratory and DNA from cells transformed with hybrid plasmids in a CII laboratory.

## A 3-s delay in an optical burst from X-ray burst source MXB1735-44

THE discovery of optical bursts from the X-ray burst source MXB1735-44 was reported in a previous article<sup>1</sup>. One burst event was detected in both X rays and optical light. We showed (in Fig. 1 of the earlier article) that the optical burst is delayed by  $\approx 1.5$  s relative to the X ray burst. We concluded that to within the accuracy of the SAS 3 quick-look data timing ( $\pm 1$  s), the onset of the optical burst was coincident with that in X rays. A few months after the completion of our earlier paper, SAS 3 production data became available. We here report a re-analysis of the arrival times of the X ray and optical bursts based on these data which contain the universal time to an accuracy of  $\leq 5$  ms. We now find (as shown in Fig. 1) that the optical burst is delayed significantly by 2.8 s.

The optical observations were performed using the 1.5-m telescope at the Cerro Tololo Interamerican Observatory and a red-blocked RCA 31034 photomultiplier tube which had an

effective bandpass including the transmission of the atmosphere of 3,100-5,500 Å (FWHM). The absolute time, which was maintained to within 10 ms of UT by monitoring WWV, and the optical data in 100-ms integrations were recorded on a digital tape. Simultaneous X-ray observations were made with the horizontal tube detectors aboard the SAS 3 observatory<sup>2</sup>. The three energy channels of interest are 3-6 keV, 6-12 keV and 8-19 keV which have time resolutions of 0.42 s, 0.83 s and 0.83 s, respectively. The X-ray production data are assigned absolute times in a three-step process. First, real time X-ray data and timing data from the spacecraft clock are tagged with the absolute time at the NASA ground station in Quito, Ecuador, by recording them simultaneously with the output of a UT caesium clock. Second, in the production analysis at Goddard Space Flight Center the real time data are used to assign UT to the bulk of the data which are played back from the on-board tape recorder. Third, corrections for the variable VHF propagation time from the satellite to the ground station are made using a satellite ephemeris based on four days of radar-Doppler track-

ing data. Atmospheric propagation delays limit the accuracy of the absolute timing of the production data to  $\pm 5$  ms of UT.

In the burst event shown in Fig. 1, the optical burst was delayed by 2.8 s relative to the 3–6-keV X-ray burst and  $\approx 2.0$  s relative to the 6–19-keV burst. Defining the moment of detection as the time of the first bin in which there is a  $\geq 3\sigma$  increase above the mean background counting rate, the burst was detected first in the 3–6-keV band at 08.22.20.2 UT. The higher-energy X rays were delayed by  $\approx 1$  s and the optical pulse was delayed by  $2.8 \pm 0.5$  s. The  $\pm 0.5$ -s uncertainty ( $\sim 2\sigma$ ) in the optical delay was derived by examining alternative binning schemes for the optical and the X-ray data which have fundamental time resolutions of 0.1 s and 0.42 s, respectively. One sigma gaussian error bars are shown in Fig. 1. Also, the exact Poisson statistical significance of the first bin to exceed  $3\sigma$  in each bandpass is given. The dotted line in Fig. 1 shows that the optical data are equally consistent with a 3-s linear rise to maximum from the time the burst was first detected or with a 3-s delay followed by an abrupt rise to maximum. The optical burst has about twice the duration of the X-ray burst. About half of the total optical burst flux was detected at a statistical significance of  $4.0\sigma$  during the 7-s interval from 08.22.25.5 to 08.22.32.5 UT, well after the X-ray flux had ceased.

The higher energy X-ray pulses are delayed  $\sim 1$  s relative to the 3–6 keV pulse and decay  $\sim 1$  s sooner. The X-ray data are consistent with a black body emitter which is heated in  $\sim 1$  s, reaches a peak temperature  $\sim 30 \times 10^6$  K and subsequently cools

**Fig. 1** X-ray/optical burst from the X-ray burst source MXB1735–44. The event was detected first in 3–6-keV X rays, as marked by the vertical dashed line, and  $\approx 2.8$  s later in blue light. The background counting rates and their approximate ( $N^{1/2}$ ) uncertainties are indicated by horizontal dashed lines and error bars, respectively. The exact Poisson statistical significance of the first bin to exceed a  $3\sigma$  detection threshold is also given. The dotted line shows that the optical data are equally consistent with a 3-s linear rise to maximum from the time the burst was first detected or with a 3-s delay followed by an abrupt rise to maximum. A large tail is apparent in the optical data (see text). *a*, Optical 3,100–5,500 Å; *b*, 3–6 keV; *c*, 6–12 keV; *d*, 8–19 keV.

in  $\sim 1$  s. This agrees with detailed studies of the X-ray spectra of several burst sources which show that the burst emission near maximum is best fitted by a  $25\text{--}30 \times 10^6$  K black body<sup>3–5</sup>.

The optical pulse is probably produced by the reprocessing of the X-ray pulse into light in an accretion disk or in the photosphere of an optical companion. The  $\sim 3$ -s delay of the optical pulse may then be attributed to one or both of the following effects: (1) light travel time in the system and (2) the time required to reprocess X rays into light. (We neglect propagation delays due to the interstellar medium which are probably negligible as shown by simultaneous optical and X-ray observations of the Crab pulsar<sup>6</sup>.) For relatively neutral matter, in the outer portion of an accretion disk ( $R \geq 1$  light s) or in the photosphere of a companion star, the reprocessing time for the bulk of the photon flux would be small ( $< 1$  s). This is a consequence of the soft ( $\sim 30 \times 10^6$  K) black body spectrum of the burst radiation discussed above. Two-thirds of the photons are below 8 keV ( $\sim 40\%$  of the energy) and would be photoelectrically absorbed by C, N and O at small optical depths<sup>7</sup>. The third of the photons above 8 keV ( $\sim 60\%$  of the energy) would be reprocessed more slowly<sup>7</sup>, and might contribute to the observed optical tail discussed above.

If the optical pulse originates in the atmosphere of a stellar companion, then it will be delayed due to light-travel time by an amount

$$\Delta T \approx L/c[1 - \cos \phi \sin i]$$

where  $L$  is the average distance of the X-ray star from the photosphere of the companion and  $\phi$  and  $i$  are the orbital phase and inclination angles, respectively. We have assumed that the orbit is circular and that the stellar radius is not too large compared with the binary separation. For any  $i$  and over the range of  $\phi$  for which a significant portion of the heated photosphere is visible ( $120^\circ \leq \phi \leq 240^\circ$  for large  $i$  and the full range of  $\phi$  for small  $i$ )<sup>8</sup>,  $\Delta T = 3$  s gives:

$$1.5 \text{ light s} \leq L \leq 6 \text{ light s}$$

or

$$0.6 R_\odot \leq L \leq 2.6 R_\odot$$

The model predicts an observable modulation ( $\geq 25\%$  for  $i \geq 15^\circ$ ) of the delay time at the orbital period. As we noted in our earlier paper<sup>1</sup>, the lack of photometric variability ( $< 0.1$  mag) in the steady optical source<sup>9,10</sup> argues against this model and suggests that an accretion disk may contribute significantly to the optical luminosity and/or shield much or all of the stellar surface.

Alternatively, the optical pulse could be produced in the outer portion of an accretion disk ( $R \sim 2\text{--}3$  light s). In this case the time delay would show at most a small modulation at the orbital period (see DQ Her in refs 11, 12). It may also be variable, if for example, the burst emission is beamed or if there are changes in the structure of the disk.

The optical pulse might also originate in the fully ionised inner portion of an accretion disk ( $R \leq 1$  light s) which is not shielded from the compact source and in which the reprocessing time is long. The results of steady-state calculations for uniform density models scaled to high densities<sup>13,14</sup> and for models of X-ray illuminated atmospheres extrapolated to high fluxes<sup>15</sup> suggest that irradiated matter within  $\sim 1$  light s of the compact source will be thick to Thomson scattering and thin to photoelectric absorption. In these conditions the burst X rays which are not reflected from the disk will undergo many Thomson scatterings, and the bulk of the optical photons will be produced at large optical depths. Detailed calculations are required to estimate how these and other reprocessing effects would determine the delays, widths, rise times and intensities of optical bursts.

## Experimental folding in ice and the resultant *c*-axis fabrics

FOLDS are commonly observed features of naturally deformed rocks<sup>1</sup> and glaciers<sup>2,3</sup>. Many different materials<sup>4</sup> have been used to model naturally occurring fold patterns. The deformation experiment described here used ice as an analogue for quartz in quartz-rich rocks by deforming a sample with an initially planar layering or anisotropy. This deformation is compared with samples of unlayered isotropic polycrystalline ice (Fig. 1a). Ice is convenient to use in the laboratory because of its relative ease of deformation at readily controlled temperatures. When used to model the behaviour of quartz-rich rocks, ice is a realistic analogue because both ice and quartz have: (1) hexagonal crystal structures; (2) exhibit similar optical properties; (3) form polycrystalline aggregates; and (4) deform using common crystallographic slip planes, particularly the (0001) basal planes<sup>5,6</sup>. In our experiments, a sample of multilayered ice consisting of plates of fine-grained ice sandwiched between layers of coarser ice (Fig. 1c) was deformed in a plane strain apparatus. The *c*-axis orientations of the grains were initially random and therefore the composite sample resembled the structure of many naturally occurring quartzites<sup>7</sup>. The experimental technique described here makes it possible to explore the relationship between initial anisotropy on folding and fabric development.

Cylinders of polycrystalline ice were prepared from a mixture of sieved ice-crushings and distilled water (details of the method will be published elsewhere). The ice contains equant grains of essentially uniform grain size with randomly orientated *c*-axes. The grain size can be controlled and for these experiments cylinders with grain sizes of 1 mm (fine grained) and 2 mm (medium grained) were produced. An irregular distribution of small air bubbles between 0.1 and 0.2 mm diameter were

**Fig. 1** a, An isotropic block of fine-grained ice with circular strain markers. b, The isotropic sample after 21% shortening and the strain markers are now ellipses. c, The planar fine- and medium-grained layers in the anisotropic block, separated by the films of frozen water. d, The anisotropic ice after 36% shortening. Voids have developed between layers (black), and air bubbles are more elongate (fine lines) in the hinge region of the fine-grained layers. Only a few elliptical strain markers have been preserved on this *XZ* face after deformation.

present at an estimated concentration of  $10 \text{ mm}^{-3}$ , in the grain boundary areas, in parts of the fine-grained ice.

Each cylinder was cut into plates  $\sim 6 \text{ mm}$  thick and also a block  $\sim 50 \times 50 \times 60 \text{ mm}$ . A composite layered block of comparable dimensions was made from the two sets of plates. After being cut flat on a Leitz microtome, the surfaces of each plate were coated with a 1% solution of polyvinyl formate (Formvar) dissolved in ethylene dichloride and allowed to dry for 12 h. The surfaces were then frozen together with a film of distilled water to produce an anisotropic block of alternate fine- and medium-grained layers (Fig. 1c).

**Fig. 2** Displacement-time curves for blocks of fine-grained (a) and medium-grained (b) isotropic ice shortened by 27% and anisotropic ice (c) shortened by 36%.

Strain markers consisting of circular grooves 5 mm diameter, 0.4 mm deep and 0.3 mm wide, were inscribed at 10 mm centres on the *XZ* faces of the three blocks. (Here the extension direction is *X*, the direction of no length change *Y*, and *Z* is the shortening direction). The blocks were then deformed in a plane strain apparatus similar to those described by Kamb<sup>8</sup>, and Budd and Matsuda<sup>9</sup>. The layers in the composite block were parallel to the *YZ* plane. The load on the layered block was 83 kg and that on the isotropic samples 150 kg and so the initial stresses were 0.4 MPa and 0.6 MPa respectively. During loading and unloading the temperature was typically  $-10^{\circ}\text{C}$ , and for the deformation it was controlled to  $-1.00 \pm 0.05^{\circ}\text{C}$ . The displacement-time curves of the fine-grained and medium-grained isotropic ice are of a similar decelerating form, whereas the more lightly loaded anisotropic sample deformed at an increasing rate after 20% shortening (Fig. 2). This is presumably attributable to buckling and increasing instability of the layers.

The isotropic ice deformed homogeneously on a scale greater than a few grain diameters. The numerous small amplitude undulations (parallel to *Y*) that formed on the *YZ* faces of both the fine- and medium-grained samples are the only inhomogeneities observed, and have amplitudes and wavelengths of the order of the average grain size. The uniform distortion of the circular strain markers into a set of ellipses suggests that extension in the *X* direction was uniform. The bubbles in the fine-grained sample were elongated parallel to the strain ellipses. Grain sizes were uniform and boundaries were slightly irregular. Occasional deformation bands developed in individual grains as sharply delineated, wide lamellae. The *c*-axis orientation patterns of deformed fine- and medium-grained isotropic samples were similar (Fig. 3a and b), and were found not to vary throughout each sample. The majority of *c*-axes are distributed between the 25 and 45° cones centred about the shortening axis. This pattern is also consistent with other plane strain experiments with shortenings of greater than 40% (unpublished data).

**Fig. 3** *c*-axis patterns of preferred orientation. (a) and (b) show the fine- and medium-isotropic ice shortened by 27%. (c) and (d) show the fine and medium layers in the anisotropic ice shortened by 36%. The data are plotted on the lower hemisphere equal area projection and the superimposed small circles are at angles of 25° and 45° to the shortening axis *Z*. The number of *c*-axes is shown adjacent to the projection.

**Fig. 4** Microstructure in the folded fine- and medium-grained layers of the anisotropic ice. An interlocking grain aggregate in the fine layers is in marked contrast to the large grains of the medium layers.

The anisotropic specimen deformed inhomogeneously and large symmetric sinusoidal folds were produced in the medium- and fine-grained layers (Fig. 1d). The folds are disharmonic and their axial surface lies approximately perpendicular to the direction of shortening. Folds in the outer layers are parallel and penetrative, and their hinge lines make a 20° angle to *Y* (in the *XY* plane). Fold amplitude and sense of closure change in the *Y* direction in the central portion of the block, where dilation voids also appear between layers. The thin ice films used to bond the fine- and medium-grained layers together have also been folded, partly in conformity with adjacent fine- and medium-grained layers. However, adjacent to the voids the ice films display minor folding where axial surface orientations vary from perpendicular to parallel to the shortening direction.

The strain distribution within individual layers is inhomogeneous with the strain ellipses being distributed about the axial surface of the major folds. Where an original circle lay across the boundary between a fine- and medium-grained layer it was either significantly elongated in the fine layer or displaced parallel to the layer boundary. The small air bubbles in the fine-grained layers are elongate and describe a symmetric fan-like pattern.

In the anisotropic ice sample the relative grain size difference between adjacent layers has been preserved. Grain shapes are quite irregular and grain diameters have increased (Fig. 4). In the fine layers the average grain size is 1.5 mm, and in the medium layers grains vary from 2.5 to 4.5 mm. Nearly every grain contains undulose extinction or deformation bands. The *c*-axes in both the fine and medium layers (Fig. 3c and d) are distributed throughout the projection with a strong maxima parallel to the shortening direction. Such a pattern is a significant departure from the small circle distribution of the isotropic samples. An axial distribution analysis<sup>10</sup> of the anisotropic samples suggests that there is no relationship of *c*-axis orientation to relative position in the fold. The pattern of *c*-axes is consistent with some patterns recognised in natural<sup>7</sup> and experimentally deformed<sup>11</sup> polycrystalline aggregates of quartz and also natural ice<sup>12</sup>.

Folding induced by an initial layering produces a different fabric from a homogeneously deformed polycrystalline aggregate. This effect on fabric development has not been considered in other experimental studies of either ice or quartz, nor in any of the computer simulations of fabrics<sup>13,14</sup>. The displacement of strain markers between layer boundaries, the variable axial-surface orientations associated with the minor folds, and their partial parallelism to the layer boundaries, suggest that during the deformation there has been some degree of layer boundary slip. Therefore buckling and flattening proceed simultaneously with layer boundary slip and a component of plane strain. This compares markedly with the isotropic samples where the deformation is strictly a homogeneous plane-strain deformation. It is the layering then that is crucial in determining the deformation path of any point in the material.

## Thiocyanate in Red Sea brine and its implications

THE Oparin–Haldane hypothesis about the origin of life has provided a rational theoretical model for laboratory research. Almost thirty years of experiments have supported this hypothesis. Verification of the hypothesis in terrestrial environments, however, has not been documented. Some environments such as thermal springs in the Kuril Islands have been reported to have possible chemical precursors but lack of sterility and other factors have not made it possible to establish evidence for natural, terrestrial abiotic synthesis<sup>1</sup>. We identify here the Atlantis II Deep brine as a promising site for searching for chemical precursors, report finding thiocyanate in the brine and suggest a relationship between chemical evolution and the evolution of the Earth's crust.

We have recently suggested<sup>2</sup> that the Red Sea brines, located at the bottom of the sea in the rift valley of an active axis of spreading global plates, might be a fruitful place to search for terrestrial evidence of abiotic synthesis of life precursors<sup>2</sup>. The Atlantis II Deep brine (21°22' N, 38°05' E) was thought to be especially promising because: (1) it has been reported sterile<sup>3</sup>; (2) it has a methane enrichment 10<sup>3</sup> times normal seawater<sup>4</sup>; (3) it has no free oxygen (O<sub>2</sub>)<sup>5</sup>; (4) it is unusually warm (63 °C) (D. A. Ross, personal communication); and (5) it has been reported as a 'reducing' environment<sup>5</sup>.

During Cruise 93, Leg 19 of the RV Atlantis II in spring 1977 the Atlantis II Deep brine was identified by seismic profiling and depth recording revealing a brine of about 200 m thickness at a depth of 2,000 m. Water samples were collected using 10 l and 30 l Niskin samplers set at 7 m intervals from 14 m above the bottom to 225 m above the bottom at Station 87. Our samples were subsequently stored in sealed, sterilised, brown, opaque Nalgene bottles and thymol crystals were added to half to ensure continuous sterility. Sterility of the samples taken at this station from the brine has been confirmed (R. Cuhl, personal communication).

Aliquots (5 cm<sup>3</sup>) of Bottle no. 1 (30 l) from Station 87 were chromatographed using butanol/ammonia/water on Whatman no. 1 paper<sup>7</sup>. The *R<sub>f</sub>* of known thiocyanate was 0.25 in these conditions. Strips of 4 cm length corresponding to the *R<sub>f</sub>* of known thiocyanate were cut, eluted with 5 cm<sup>3</sup> of distilled water and flash evaporated to their original volume. Aliquots of 0.5 cm<sup>3</sup> were tested for thiocyanate using 0.3 cm<sup>3</sup> 0.1 M cupric chloride solution and 0.5 cm<sup>3</sup> of a ferric nitrate/nitric acid reagent. Thiocyanate produces a wine red colour with these reagents and a spectrophotometric absorbance peak at 4,600 Å

(ref. 8). (This analytical method was developed to measure thiosulphate by adding cyanide to produce sulphite and thiocyanate. The reagents are added to produce a ferric thiocyanate complex. The thiosulphate concentration corresponds to the absorption of the complex. We used this method as a direct measure of thiocyanate. Thiosulphate without cyanide produces no spectrophotometric absorbance with these reagents.)

The Atlantis II Deep brine samples were analysed against a 'null' brine of 5M NaCl, 0.2M KBr and 0.02M KHCO<sub>3</sub> on a Zeiss ZFM 4/v4QIII/PMQII spectrophotometric system and a Unicam SP80 recording spectrophotometer. The spectra of the samples were scanned from 4,300 Å to 6,000 Å and compared with the spectrum of known ferric thiocyanate complexes with respect to general shape and the absorption ratios at several wavelengths. Aliquots (5 cm<sup>3</sup>) were chromatographed, eluted and concentrated to one-tenth the original volume and analysed. Results of the direct analysis confirm a thiocyanate concentration of 2.4 × 10<sup>-5</sup> M (mean of 12 spectrophotometric analyses; standard deviation = 1.2) in the Atlantis II Deep brine. No thiocyanate was detected in a control sample of Red Sea water.

In four experiments, a known amount of thiocyanate was added to the brine to determine whether this would increase the spectrophotometric absorption corresponding to the amount added. This was confirmed in all four experiments. Results of these experiments yield a mean thiocyanate concentration of 2.8 × 10<sup>-5</sup> M (range 2.3–4.0 × 10<sup>-5</sup> M) in the brine. This concentration is significant from the point of view of prebiotic chemistry.

Some samples were also treated with Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> before analysis to test for the presence of cyanide ions<sup>8</sup> but none were found. All cyanide, however, would be expected to convert to thiocyanate since the underlying sediments through which the brine flows are rich in elemental sulphur and sulphides such as pyrite, chalcocopyrite, sphalerite and marcasite<sup>9,10</sup> making the environment similar to conditions for the commercial preparation of thiocyanate from cyanide.

What is the origin of the thiocyanate in the Atlantis II Deep brine? No marine organisms are known to release cyanide or thiocyanate into the marine environment. Both cyanide and thiocyanate have been reported from geothermal springs<sup>1</sup>. Hydrogen cyanide may have been formed abiotically and released from within the ridge system after which it reacted with sulphur or sulphides to form thiocyanate. We think this is the most likely source of the thiocyanate.

The important role of hydrogen cyanide and its related chemical species in the prebiotic synthesis of purines, pyrimidines and amino acids is well-documented from Miller<sup>11</sup> to Ferris and Joshi<sup>12</sup>. The discovery of thiocyanate in a sterile, natural terrestrial environment such as the Atlantis II Deep brine is consistent with our suggestion that there may be a relationship between the evolution of the Earth's crust at spreading axes and the origin of life. While the presence of thiocyanate in a sterile brine does not equivocally demonstrate the abiotic origin of the cyanide from which the thiocyanate may derive, it suggests that further analysis of the Atlantis II Deep brine should be undertaken to assess the character of organic molecules present. Previous analysis of hydrocarbons in the brine has indicated pronounced enrichment in methane, ethane and low molecular weight paraffins<sup>3</sup>. Abiotic synthesis of amino acids in this environment is plausible.

Criteria for determining whether amino acids were formed biotically or abiotically include the D and L enantiomer ratio, the <sup>13</sup>C and <sup>12</sup>C ratio and the type of amino acids present<sup>13</sup>. As the brine has a high temperature, the D and L enantiomer ratio may not be a useful criterion. Amino acids such as α-aminoisobutyric acid, α-amino-n-butyric acid, N-ethylglycine, N-methylalanine, norvaline and sarcosine in amounts similar to those found on the Murchison meteorite would suggest an abiotic origin. We intend to search for amino acids in the Atlantis II Deep brine and will use these criteria in our evaluation.

We thank Dr D. A. Ross of Woods Hole Oceanographic Institution for enabling us to acquire the brine samples and to participate in Cruise 93, Leg 19 of the RV Atlantis II and Dr L. E. Orgel for laboratory space and advice. We acknowledge financial support from NSF-OCE-76-10417, NSF-SPI-78-19097 and the San Diego State University Foundation.

## Origin of carbonatites by liquid immiscibility

THE existence of carbonatite magmas has been generally accepted<sup>1</sup>, but their origin remains uncertain. The more favoured petrogenetic models include: (1) direct partial melting of the upper mantle<sup>2–5</sup>; (2) fractional crystallisation of CO<sub>2</sub>-rich alkaline silicate magma<sup>6</sup>; and (3) separation of an immiscible carbonate melt from an initially homogeneous CO<sub>2</sub>-rich alkaline silicate magma<sup>7–10</sup>. Experiments have shown all of these processes to be feasible<sup>5–7</sup>, and each may generate the geochemical characteristics of carbonatite, such as enrichment in rare earths and other incompatible trace and minor elements<sup>11,12</sup>, and low <sup>87</sup>Sr/<sup>86</sup>Sr ratios<sup>13</sup>. Here we discuss the role of immiscibility, and report new experimental data which demonstrate for the first time that liquid immiscibility does occur between silicate and carbonate liquids of the compositions found in nature.

While previous experimental work suggests that high concentrations of Na<sub>2</sub>O are required for immiscibility<sup>7,14,15</sup>, the great majority of analysed carbonatites are rich in CaO with Na<sub>2</sub>O as only a minor constituent, seemingly ruling out a role for immiscibility in their genesis (for example, mean of 12 Kenyan alvikites CaO = 50.83, Na<sub>2</sub>O = 0.48 wt % ref. 9, p. 317). However, it has been argued that the present-day compositions of most carbonatites are not representative of the original magmas but have lost large quantities of alkali oxides during fenitisation and due to leaching by meteoric waters<sup>2,3,9,16,17</sup>. This view is supported by the study of inclusions in minerals from carbonatites, which show that alkaline CO<sub>2</sub>-rich fluids were present at high temperatures<sup>18–20</sup>. It is significant that the only carbonatite which has been observed at the time of eruption, the natrocarbonatite of Oldoinyo Lengai, Tanzania<sup>21–25</sup>, contains about 30 wt % Na<sub>2</sub>O (Table 1). This lava has retained its alkalis

**Fig. 1** Spheres of carbonate in silicate glass. The diameters range up to about 2 mm. The small pits seen in the carbonate are probably CO<sub>2</sub> vesicles. Starting material was 15% carbonate plus 85% nephelinite, run conditions 2 kbar, 1,000 °C for 18 h.

because it reached the surface and quenched, precluding fenitisation processes, and because it was sampled before it had been leached. Xenoliths of plutonic carbonatite from the same volcano are CaCO<sub>3</sub>-rich sövite<sup>24</sup>. The main aim of the present study was to investigate the possibility of an immiscibility relationship between the Oldoinyo Lengai natrocarbonatite and the contemporaneous silicate magmas.

Two synthetic carbonatite compositions were made up, one a simplified version of the Oldoinyo Lengai lava, and the other richer in CaCO<sub>3</sub> (Table 1). These were mixed and ground in various proportions with two powdered silicate lavas from Oldoinyo Lengai, a phonolite and a nephelinite (Table 1). About 0.7 g samples of dried powder were sealed in noble-metal tubes and run at pressures from 0.7 to 7.6 kbar and temperatures from 900 to 1,250 °C in argon-filled internally heated pressure vessels. Selected run data are given in Table 1.

In general, charges which were not of extreme composition (that is, very close to either silicate or carbonate starting materials) showed characteristics on quenching consistent with the coexistence of two melts at the pressure and temperature of the experiment. Silicate melts quenched to glasses, which were separated by smooth, sharp menisci from carbonate melts, which quenched to crystalline aggregates. The actual geometry of the association depended on the proportion of carbonate in the starting mixture, and the temperature and pressure of the run. Where the proportion of silicate greatly exceeded that of carbonate, globules of carbonate were observed in silicate glass, see, for example, Fig. 1. Where there was a moderate to high proportion of carbonate, however, (≥40 wt %), a central ovoid slug of silicate glass normally occurred, flanked by ends of carbonate. Depending on temperature, a small number of globules of one phase was observed in the other, but at temperatures ≥1,000 °C almost complete separation of melts took place.

Where a significant amount of crystals are present in the silicate melt the physical separation of the two melts is not so perfect. In 50/50 original mixtures of silicate and carbonate the final geometry of the charge was still a central lozenge of silicate glass with two end cappings of carbonate but significant amounts of carbonate globules occurred throughout the silicate glass. The larger volumes of carbonate remain essentially silicate-free, however, and it was easy to hand pick a silicate-free carbonate fraction. This was analysed by wet chemical methods. The silicate glass was analysed by electron microprobe. Microprobe

analysis of the carbonate fraction using a defocused beam generally gave broadly comparable results with the wet chemical analysis, but was considered less reliable because of the instability of the carbonates. However, it did allow some supplementary data to be obtained on elements which were not analysed wet chemically.

Several features suggest that the phases we have analysed represent equilibrium immiscible melts and are not just the result of the failure of the starting mixtures to homogenise. These include: (1) scanning electron microscope study of the charges shows that the meniscus between the melts is sharp on a submicron scale; (2) the silicate glasses are compositionally homogeneous throughout the slugs; (3) spheroids of silicate glass, ~100  $\mu\text{m}$  diameter, in the quenched carbonate melts have compositions identical to those of the main silicate slugs; (4) spheroids of quenched carbonate liquid in the silicate glass, a few tens of  $\mu\text{m}$  diameter, yield microprobe analyses which are comparable to the wet chemical analyses of the main carbonate fraction, bearing in mind their instability in the electron beam. We have also carried out reversal type experiments to test for gross metastability. In the first instance, two melts were held at conditions where the miscibility gap is narrow (high  $T$ , low  $P$ ), so that the silicate dissolved large amounts of carbonate. The homogeneous silicate-glass fraction was removed and re-run in conditions where the miscibility gap is wide (low  $T$ , high  $P$ ) and it exsolved small spheres of carbonate. Second, it was found that silicate glass containing a few spheroids of carbonate (~0.1 mm diameter), produced at high  $P$  and low  $T$  could be homogenised by re-running at low  $P$  and high  $T$ . These experiments demonstrate that the carbonate melt would readily dissolve, or exsolve from the silicate melt in the conditions of interest in this study.

The main characteristics of the immiscibility field encountered in this study are shown in Table 1 and Fig. 2. The components of Fig. 2,  $\text{SiO}_2 + \text{Al}_2\text{O}_3$ ,  $\text{Na}_2\text{O} + \text{K}_2\text{O}$ ,  $\text{CaO}$ , represent ~90% of the  $\text{CO}_2$ -free portions of both melts. Most of the data are for one temperature, 1,100 °C, but for three pressures, 0.7, 3.0 and 7.6 kbar. Conjugate melts at both 0.7 and

**Fig. 2** Miscibility gap between carbonate and silicate melts. Conjugate melts are shown for 0.7 kbar, 1,100 °C (■); 3.0 kbar, 1,100 °C (×); 7.6 kbar, 1,100 °C (●); and 3.0 kbar, 900 °C (\*). The boundary between the one-liquid and two-liquid fields has been drawn for each pressure and 1,100 °C. Conjugate liquids at 0.7 kbar and 7.6 kbar are joined by tie-lines. The liquids furthest from the CaO apex were produced from mixtures of phonolite and CaO-poor carbonatite, those closer to the CaO apex were produced from mixtures of nephelinite and CaO-rich carbonatite. P, Oldoinyo Lengai phonolite; N, nephelinite; L, natrocarbonatite.

7.6 kbar are joined by tie-lines. The data points for each pressure are joined by curves which represent the isothermal, isobaric phase boundaries between the one-liquid and two-liquid fields (Fig. 2). The data indicate that the miscibility gap closes towards the CaO apex; this is supported by data on other systems, for example, immiscibility was not found in  $\text{NaAlSi}_3\text{O}_8\text{-CaCO}_3\text{-H}_2\text{O}$  at 1 kbar (ref. 6). Therefore, we have extrapolated the field boundaries and shown the closure as dashed lines (Fig. 2). Comparison of the boundary curves shows that increasing pressure expands the miscibility gap. The inclusion on Fig. 2 of a run at 3 kbar and 900 °C shows that decreasing temperature expands the two-liquid field in a manner analogous to increasing pressure. It is stressed, however, that the effect of changing  $P$  or  $T$  is not just a simple narrowing or widening of the gap but complicated changes in composition take place including rotation of the tie-lines.

The compositions of Oldoinyo Lengai phonolite (P), nephelinite (N) and carbonatite (L) are also shown in Fig. 2. The position of the tie-lines suggest that the natrocarbonatite is likely to have been immiscible with a phonolitic magma at high pressures and temperatures. Nephelinite melt, on the other hand, was consistently found to be immiscible with carbonate melts much richer in CaO than the Oldoinyo Lengai lava (Table 1, Fig. 2). Therefore the experimental study supports the view<sup>25</sup> that the Oldoinyo Lengai carbonatite exsolved from a  $\text{CO}_2$ -rich phonolitic magma.

Most natural carbonatite compositions lie close to the CaO apex of Fig. 2, and it seems unlikely that the tie-lines could rotate sufficiently for phonolitic or nephelinitic magmas to be conjugate with carbonate melts so poor in  $\text{Na}_2\text{O}$ , even at very high pressures. If these carbonatites did originate by immiscibility, then significant loss of alkalis must have occurred at some stage in their development, as proposed above. The failure of many experimentalists to observe immiscibility during experiments on  $\text{CO}_2$ -rich systems at pressures to 30 kbar<sup>6,14,15</sup>, or to confirm the presence of immiscibility which had been tentatively identified<sup>26,27</sup>, is because the compositions studied were poor in

\* Total iron as FeO.

Na<sub>2</sub>O, and plotted in the one-liquid field of Fig. 2. However, the compositions of many mafic and ultramafic alkaline igneous rocks, such as melanephelinites, melilitites, kimberlites and alnoites, also project into this field, suggesting that the corresponding magmas are unlikely to exsolve carbonate melts at crustal pressures, although immiscibility in the mantle remains a possibility.

The experimental work was undertaken at Manchester University within the experimental petrology group which is financially supported by the NERC. We thank Dr J. Esson and T. Jensen for arranging the analysis of the carbonates. The analyses of the lavas were carried out at the University of St Andrews during the tenure of a NERC grant to J. B. D.

## Variation in apatite composition in ijolitic and carbonatitic igneous rocks

WE present here evidence that apatite crystals formed in alkaline magmas during the early stages of both the ijolitic (pyroxenite → ijolite → urtite) and carbonatitic (sövite → alvikite) differentiation series<sup>1</sup> have similar chemical compositions, but that with subsequent crystal differentiation in both series, the compositions of the apatites can change progressively along two separate paths. The evidence of a bifurcating pattern of apatite compositions from the various rock types studied is not in accord with the theory<sup>2,3</sup> that carbonatites are the ultimate product of fractional crystallisation of the ijolitic series. The evidence suggests that ijolite and sövite are the crystalline products of conjugate immiscible liquids.

Any wet chemical method of apatite analysis relying on mineral separation techniques introduces the possibility of contamination<sup>4</sup>, and hence many published apatite analyses must be considered suspect. Electron microprobe (EMP) analysis, however, can provide good quality data, and minor chemical variations can be used as reliable indicators of fractionation processes<sup>5</sup>. Our data show greater variation in chemical composition than was previously indicated<sup>6</sup>.

The means of 115 EMP analyses of apatites in Table 1 are taken from five associated rock types from two adjacent well documented strongly alkaline igneous complexes<sup>1</sup>. Very similar analytical data have been obtained from other igneous and sub-volcanic complexes in this west Kenyan-east Ugandan-north Tanzanian Tertiary magmatic province. It seems that the apatites from any one particular rock type and texture all have the same chemical composition, no matter which igneous complex they are taken from in the province. Apatites, like other igneous minerals, seem to reflect chemically the nature of the liquids from which they were precipitated.

The five rock types mentioned under Table 1 provide good representatives of the ijolitic and the carbonatitic differentiation

**Fig. 1** Variation diagram for apatites from ijolitic (—○—) and carbonatitic (—△—) rocks. Oxides and fluorine plotted in wt %: La in p.p.m. Σ<sub>ox</sub> is sum of Na, Ce, La, Sr oxides. Arrows show direction of differentiation. P, pyroxenite; I, ijolite; U, urtite; S, sövite; A, alvikite.

2 From ijolite, Usaki, West Kenya (U 1256).

3 From urtite, Usaki, West Kenya (U 79).

4 From sövite, North Ruri, West Kenya (N 43).

5 From alvikite, North Ruri, West Kenya (N 179).

series. The pyroxenite is a product from an earlier partly cumulative stage in the ijolitic differentiation series than is represented by ijolite. The ijolite (comprising mainly nepheline and aegirine-augite) is the approximate plutonic equivalent of a nephelinitic magma, whilst the urtite (largely composed of nepheline) is the fractionation product. These three represent a typical sequence of the ijolitic magmatic differentiation series as recognised at most ijolite intrusive complexes<sup>1,3</sup>. The sövite is the earliest and main member of the carbonatite series, and the alvikite is the second member of the series derived from the sövite by magmatic differentiation<sup>1,7</sup>.

The structural formulae of the five mean apatite analyses (Table 2) are calculated on the basis of 10 ions in the calcium position<sup>8</sup> rather than to 26 anions. This allows an estimate to be made, by difference, of the carbonate content of the apatite, based on the assumption that CO<sub>3</sub> groups substitute for PO<sub>4</sub> groups in the lattice<sup>9</sup>.

The substitution inferred of P by Si in notable amounts is real because most of the apatite crystals analysed from silicate rocks were single crystals mounted in resin, and that the apatite crystals were checked for lack of inclusions such as sometimes exist in these crystals<sup>10</sup>. The increasing proportion of Si with differentiation in the carbonatitic apatites is in keeping with the fact that free silica is commonly developed in late-stage carbonatites<sup>1</sup>. The reliability of the estimate of the hydroxyl content is less certain, although the F determinations in Table 1 have a good precision and Cl was below the detection limit (100 p.p.m.). The elements Mg, Fe and Mn were also sought but were below the minimum detection limit (all near 200 p.p.m.), as was Ba (500 p.p.m.).

The distinctions between the silicate and carbonate differentiation series, which are reflected in the chemical variations of the apatites, are best seen in Fig. 1. Figure 1a-d show the divergence of the two trends, e and g show that grouping of some elements produces parallel trends but still shows the proposed common parentage, and f shows that the apatites from the silicate rocks can exhibit more extreme fractionation than those from the carbonatites: a situation which could not arise if the carbonatites were a fractionational crystallisation product of the ijolitic magma. Two further significant features of all the plots in Fig. 1 are that both trends have a common starting position, and that this position is near that for ijolite and sövite which are themselves considered to be the sub-volcanic materials most closely related to the parental compositions of the two differentiation series.

The close similarity in composition of the apatites from both ijolite and sövite shows that the relationship between the two liquids from which these two rocks crystallised could have been that of a pair of liquids in equilibrium with each other. It has already been suggested that the ijolitic and carbonatitic rock series are related by liquid immiscibility<sup>1,11</sup> but, as far as we know, this is the first time that liquid immiscibility has been shown to be possible in natural alkaline igneous rocks based on the occurrence of one mineral phase, apatite, being in equilibrium with two liquid phases. This test for liquid immiscibility was recognised by Bowen<sup>12</sup> when he stated "Not only are they (the immiscible pair of liquids) in equilibrium with each other but they both must be in equilibrium with any additional phase".

The variable distribution of major and minor elements in apatites within ijolitic and carbonatitic alkaline igneous rocks

Table 2 Ions on basis 10 (Ca, REE, Sr, Na) for apatite analyses in Table 1

	1	2	3	4	5
Si	0.11	0.09	0.10	0.05	0.34
P	5.67	5.76	5.87	5.76	5.53
Ca	9.92	9.89	9.77	9.87	9.74
Sr	0.06	0.09	0.19	0.07	0.09

Na	0.02	0.01	0.01	0.03	0.03
F	1.11	1.68	1.76	1.65	1.91
(CO <sub>3</sub> )	0.22	0.15	0.03	0.19	0.13
(OH)	0.89	0.32	0.24	0.35	0.09
(O, OH, F)	26.39	26.58	26.88	26.52	26.56

show that their respective differentiation trends follow two independent paths, both emanating from magmatic compositions which could have been in equilibrium with each other. This relationship is consistent with liquid immiscibility rather than crystal fractionation as the governing petrogenetic process.

We thank R. N. Wilson for technical help, Drs M. J. Norry and A. R. Woolley for constructive criticism, and the NERC for financial support.

## First results from the Reykjanes Ridge Iceland Seismic Project 1977

PALAEOGEOGRAPHIC reconstructions of the North Atlantic area, based on plate tectonic principles<sup>1-3</sup>, suggest that Iceland is of pure oceanic origin as Greenland and Europe (including Rockall Plateau) seem to have been closely connected before 56 Myr BP (magnetic lineation 24). Oceanic origin is also suggested by the location of Iceland astride the axis of the Mid-Atlantic Ridge, by its surface geology and by the young age (16 Myr) of its oldest rocks. Further evidence comes from refraction seismic investigations<sup>4</sup> yielding a layering of the Icelandic crust resembling the typical oceanic crust in velocity values, but with greater thickness of individual layers. A remarkable result was the discovery of a layer with *P*-wave velocities close to 7.2 km s<sup>-1</sup> at a depth of 8–15 km, which was interpreted as the top of an anomalous upper mantle below Iceland. According to studies of teleseismic travel time residuals<sup>5,6</sup>, as well as apparent velocity measurements of *P*-arrivals from Mid-Atlantic Ridge earthquakes<sup>7</sup>, this anomalous mantle may extend to 240 km depth. A very different model, however, has been derived from more recent long range refraction seismic measurements<sup>8</sup>. It is characterised by a more or less continental deeper crust and a normal upper mantle with a *P*-wave velocity of 8.0 km s<sup>-1</sup> at a depth of 50–60 km below Iceland. This model could also account for the low apparent velocities given by Francis<sup>7</sup> and, if true, would require drastic modifications of current ideas of seafloor spreading. It has been used as an argument against the possibility of any significant amount of drift at the latitude of Iceland<sup>9</sup>. Geophysical evidence from Reykjanes and Kolbeinsey Ridges<sup>10,11</sup>, on the other hand, strongly favours an oceanic origin of the surroundings of Iceland. Earlier refraction seismic measurements on the crest and western flank of the Reykjanes Ridge<sup>12,13</sup> indicate a systematic change of crustal structure with age and a crustal structure typical of oceanic basins has been found some 200 km south-east of the ridge<sup>14</sup>. All the marine refraction work so far has shown anomalously low mantle velocities (7.2–7.8 km s<sup>-1</sup>) but very little information is available on the structure of the oceanic upper mantle itself because of the limited range of the seismic

profiles. In 1977 an 800-km long seismic refraction profile was shot across Iceland and along the southeastern flank of the Reykjanes Ridge (Fig. 1). The main purpose of the experiment was to resolve the structure of the crust and upper mantle to greater depth than previously possible and to study the transition from the oceanic to the Icelandic structure. This experiment was planned and carried out by an international working group (Reykjanes Ridge Iceland Seismic Project, RRISP).

The experiment described here was a joint land-sea project with a number of shotpoints on sea and land giving a set of reversed and overlapping profile segments and large observational distances. Figure 1 shows positions of shots and receivers. Nineteen shots with charges from 0.4 to 4.0 tons were fired and recorded on land by up to 42 mobile stations of MARS-66 type<sup>15</sup> from Germany, 12 automatic stations from the Soviet Union and 35 direct recording stations of the Icelandic short period seismic network. The shots at A to F were recorded by the MARS-66 stations on the main line running from Heimaey at the southern coast mostly through the neo-volcanic zone towards the north-east. Shots G and H were observed along the southeastern coast to give a reference profile in the older part of Iceland. In the marine part ocean bottom seismographs<sup>16</sup> and anchored telemetric buoy systems with ground hydrophones<sup>17</sup> recorded series of smaller shots (50–250 kg). The shots were spaced 1.8 km apart and could be recorded to 150 km range. In addition to the 800-km long main line observed 110 km east of the ridge crest three more refraction lines were observed at sea, one parallel and closer to the ridge axis and two perpendicular to it. Most of the marine profiles were covered also by sparker, gravity, total magnetic field and narrow beam echo sounder measurements.

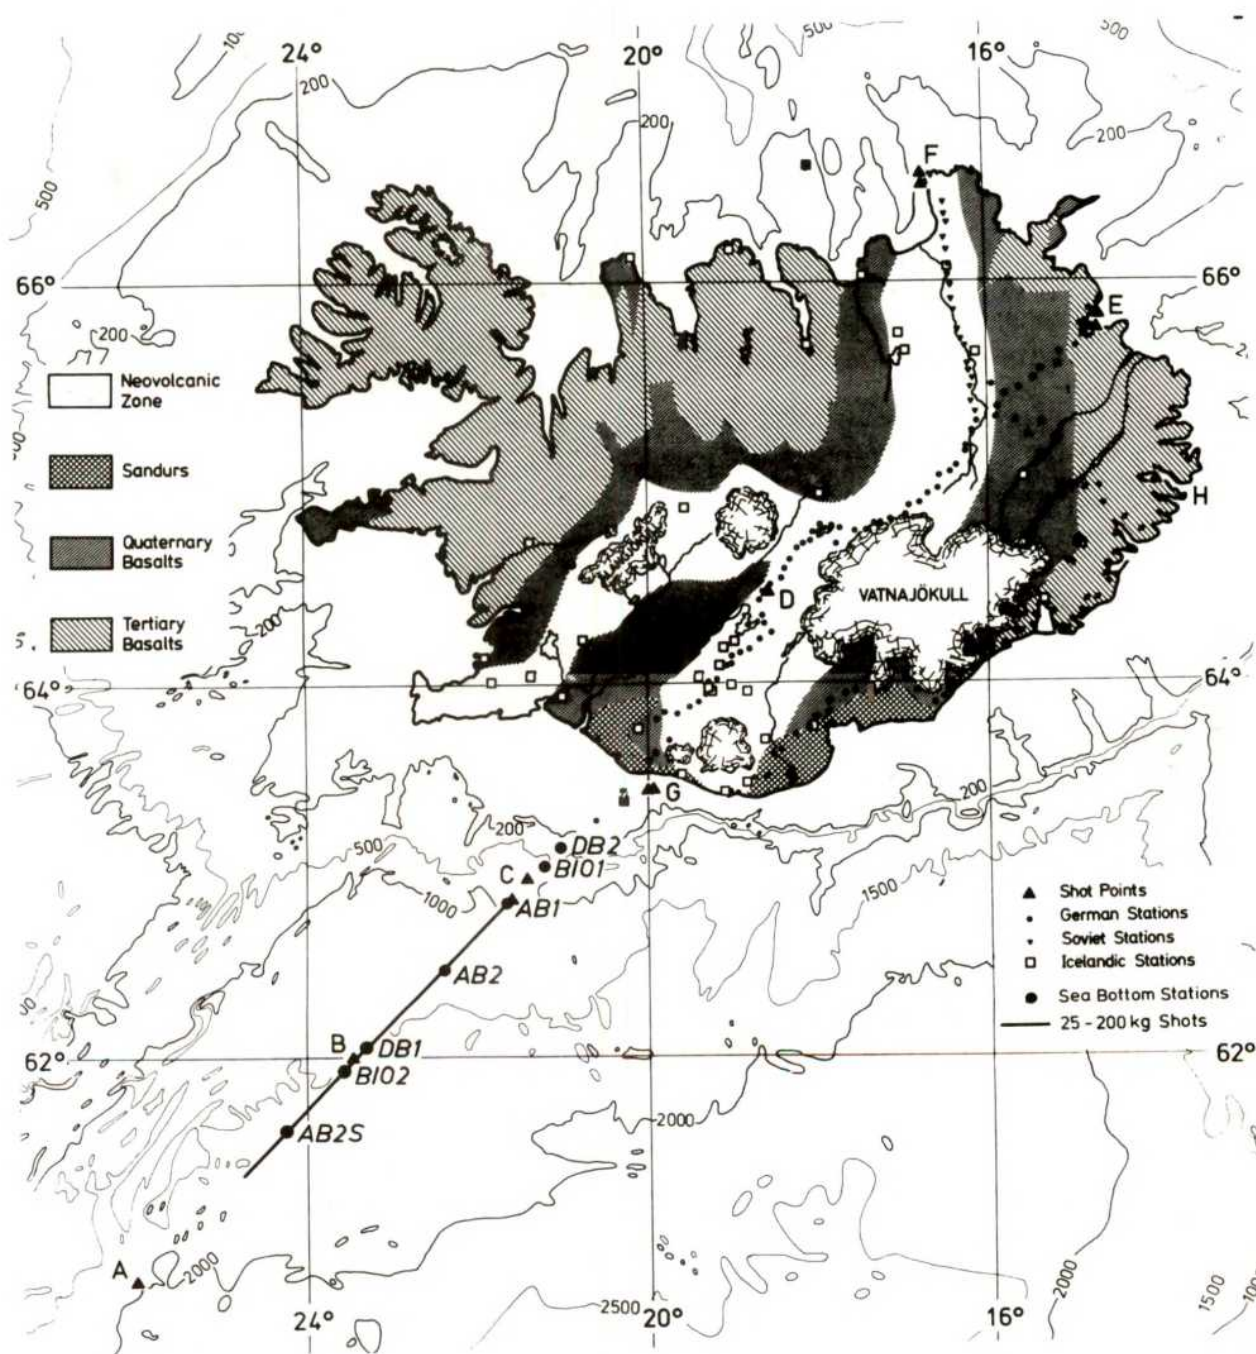

We shall concentrate on the results obtained on the main line. Figures 2 and 3 are examples of a marine and a land profile segment respectively. The upper part of Fig. 2 shows the record section (reduction velocity is 6 km s<sup>-1</sup>) obtained by shooting into the bottom hydrophone of buoy AB1 from the south-west. First arrivals can be fitted by three straight lines indicating a well defined layering of the crust. From this and the reversed line we obtain the model shown in the lower part of Fig. 2. Apart from small dips of the sea bottom and basement the layers are horizontal. The velocities and layer thicknesses are within the range of typical oceanic values. It is not known whether the velocity of 7.7 km s<sup>-1</sup> represents anomalous mantle or crustal layer 3b. From the records of OBS BI01, however, which show first arrivals with apparent velocities of 8.3 km s<sup>-1</sup> at distances greater than 90 km, it is evident that normal upper mantle is present at greater depth.

The upper part of Fig. 3 shows a typical land record section. It was obtained for shotpoint E and reduced by 7 km s<sup>-1</sup>. The record sections for shots D, F, G and H look very similar. There are distinct differences in travel time and apparent velocity within the first 100 km reflecting crustal heterogeneity but apparent velocities at greater distances are rather uniform and close to 7.0 km s<sup>-1</sup>. Clear first arrivals can be traced up to distances of 300 km, whereas later arrivals are difficult to correlate. Wave groups with apparent velocities around 8 km s<sup>-1</sup> which would indicate a normal upper mantle below Iceland can not be found. This holds also for records of the more distant shots A and B. In spite of charges of 4 and 2 tons, fired from RV Meteor in optimum water depth, only weak first arrivals were obtained from these shots at the recording sites in Iceland. As far as correlation of these arrivals is possible, again apparent velocities only slightly greater than 7.0 km s<sup>-1</sup> are obtained. On the other hand, if apparent velocities between shotpoints A, B and C are calculated for individual stations in Iceland one obtains values as high as 8.4 or even 9.0 km s<sup>-1</sup>. This is further evidence that, contrary to Iceland, the 10 Myr old Reykjanes Ridge on the seaward continuation of the profile has a well developed lithosphere. From the records of shot C, which give apparent velocities close to 8.0 km s<sup>-1</sup> for some stations near the south coast but 7.0 km s<sup>-1</sup> for more distant stations, it becomes evident that the transition from the normal lithosphere of the

Reykjanes Ridge to the anomalous deep structure of Iceland takes place near the southern shelf edge. The lower part of Fig. 3 shows our latest model with the corresponding ray paths for shotpoint E as calculated by a ray tracing method<sup>18</sup>. The calculated travel time curve has been superimposed on the record section and fits the observed arrivals well. Although the evaluation is still in progress and modifications of the model are to be expected, we feel confident with the conclusion that the P-wave velocity of  $7.0 \text{ km s}^{-1}$  is reached below Iceland in 10–15 km depth. There is no room for a 30-km thick layer with velocities from 6.5 to  $7.0 \text{ km s}^{-1}$  which could be interpreted as continental. In depths below 10–15 km the velocity increases only slightly

and velocity reversals cannot be ruled out. This anomalous layer must extend to depths greater than 60 km, as a normal upper mantle at 50–60 km depth<sup>8</sup> would produce travel time segments with apparent velocities close to  $8 \text{ km s}^{-1}$ , which have not been observed in the record sections.

On the other hand, it is known from surface wave studies<sup>19</sup> that the top of the asthenosphere is to be expected at about 60 km depth below the flank of the Reykjanes Ridge. It seems therefore most natural to interpret the anomalous layer below Iceland as a diapiric updoming of the asthenosphere and the term 'anomalous mantle' seems quite adequate. Further evidence for this interpretation comes from the observation of

**Fig. 1** Simplified geological map of Iceland and bathymetric chart of the surrounding ocean showing shotpoints and recording sites of the RRISP 77 project.

**Fig. 2** Record section of the line AB1-AB2 recorded at the ground hydrophone of buoy AB1 and reduced by 6 km s<sup>-1</sup>. The travel time curves are the ones calculated for the model in the lower part.

shear waves. The evaluation of both P- and S-waves, gives a normal ratio (1.76) for the P- to S-wave velocity in the uppermost 10–15 km, but a highly anomalous value (2.0) at greater depth, which may indicate a partially molten state of the anomalous mantle. This is also supported by magnetotelluric data<sup>20</sup>.

In conclusion, Iceland is not simply an uplifted part of the Mid-Atlantic Ridge, but rather a deep-seated anomaly. Yet it

looks much more like an extremely active part than an obstacle to seafloor spreading in the North Atlantic.

We thank all who made this experiment possible including many helpers from participating countries and the crew of RV Meteor. Iceland State Broadcasting Service made communication possible, Stefan Sigurdson helped to organise field work and Geophysikalisches Institut, Karlsruhe, made its computer available for digitising the MARS-66 recordings.

**Fig. 3** Record section on the main RRISP line from shotpoint E towards south-west, reduced by  $7 \text{ km s}^{-1}$ . The travel time curve is the one calculated for the model in the lower part and only few of the calculated rays are shown. The model is defined by lines of equal velocity, indicated by the numbers inserted, and by linear vertical interpolation between neighbouring isolines. The depth range below the  $7.0 \text{ km s}^{-1}$  isoline is interpreted as anomalous mantle.

RRISP 77 was funded through Deutsche Forschungsgemeinschaft, Orkustofnun, Soviet Academy of Sciences, Bedford Institute and NSF. The National Research Council of Iceland gave permission and support.

## Transport of molecules in concentrated systems

TRANSPORT of molecules in concentrated systems is of fundamental importance in medicine, biology and technology, for example, transport within cartilaginous tissues, the release and distribution within the body of encapsulated drugs and transport of reactants in the production process of plastic materials. These systems are usually multicomponent in nature. In all these processes the transport of substances often has a regulatory role as a rate determining step. An understanding of the transport process of macromolecules in multicomponent

**Fig. 1** Reduced diffusion coefficient ( $D_{app}/D_0$ ) of bovine serum albumin (BSA) (component 1) as a function of the concentration of Dextran T 500 (component 2; molecular weight  $5 \times 10^5$ ).  $D_0$  is the diffusion coefficient of BSA in the absence of added dextran (B. N. P. and J. D. Wells, unpublished observations).

systems is therefore essential. Although problems of this type have been treated in a few theoretical<sup>1–7</sup> and experimental<sup>8–20</sup> studies, the understanding of these systems is incomplete, especially for concentrated solutions. It is known from studies of diffusion in binary systems that a number of features of the transport process appear that do not show up in more dilute systems<sup>7,10,18–20</sup>. We present here new data for macromolecular systems which show that the diffusion rate of one macromolecule can be 'paradoxically' increased considerably by adding a sufficient amount of a suitable second macromolecular component. An interpretation of this effect is advanced in terms of an extension of existing theories of concentrated solutions.

The following discussion will be restricted to one homogenous phase, ignoring, for the moment, transport across phase boundaries such as membranes. The results apply, however, to transport inside a living cell or in the region between cells or inside a membrane.

The rate of diffusion transport<sup>1,21</sup> (diffusion flow,  $J$ ) in a binary system (solute + solvent) is determined by the value of the diffusion coefficient,  $D$ , and by the gradient in solute concentration,  $c$ , according to the relationship

$$J = -D \text{ grad } c \quad (1)$$

For a given concentration gradient (in living matter a steady state situation is often prevalent) the flow rate is determined by the numerical value of  $D$ . This coefficient depends on the thermodynamic as well as the hydrodynamic properties of the system according to the expression<sup>1,7,21</sup>

$$D(c) = \frac{k \cdot T}{f(c)} \cdot Q(c) \quad (2)$$

where  $Q(c)$  is a thermodynamic quantity, essentially the derivative of the virial expansion for the osmotic pressure, and  $f(c)$  the frictional coefficient, a hydrodynamic parameter which is a measure of the flow resistance exerted by the medium on the solute.  $k$  is the Boltzmann constant, and  $T$  absolute temperature. When concentration increases both the 'thermodynamic factor'  $Q(c)$  and the 'hydrodynamic factor'  $f(c)$  usually increase and it is the interplay between these two quantities that determines the concentration dependence of  $D$ . The numerical values of  $Q$  and  $f$  and their functional form in terms of  $c$  depend on solute-solvent system, on the size and conformational properties of the macromolecular solute as well as on temperature and pressure. For macromolecules,  $Q$  is often the dominant factor and both the diffusion coefficient and the thermodynamic driving force may change by powers of 10 when the concentration is increased from infinite dilution to, say, 10% by weight<sup>18</sup>.

In multicomponent systems the situation is more complex due to the coupling of flows and the possibility of thermodynamic

interaction between solutes<sup>22</sup>. In a ternary system (solute 1 + solute 2 + solvent), for instance, there are two independent flows,  $J_1$  and  $J_2$ , and four diffusion coefficients related through the Onsager reciprocal relationship, thus leaving three of them as independent quantities. However, if in such a ternary system the concentration of solute 1 is low and if the interest is focused on how the rate of transport of this solute is affected by successive additions of solute 2, expressions of the general form (1) and (2) can still be used<sup>24</sup> as good approximations of reality.  $D$  is then to be interpreted as an apparent diffusion coefficient,  $D_{app}$ , governing the flow of component 1.

$D_{app}$  depends on both the thermodynamic and the hydrodynamic interaction between solutes. Although there is a lack of systematic studies of thermodynamic interactions, certain osmotic pressure and light scattering data<sup>23-25</sup> obtained for ternary systems indicate that in the case of two different chain polymers the interaction is strong (large excluded volume effects) and increases considerably with increasing concentration of one or both of the solutes (successively higher order

**Fig. 2** Reduced diffusion coefficient ( $D_{app}/D_0$ ) of polyvinylpyrrolidone (PVP) (component 1) as a function of the concentration of Dextran T 10 (component 2;  $MW = 10 \times 10^4$ ). ●, PVP 360 ( $\bar{M}_n = 3.2 \times 10^5$ ); ▼, PVP 40 ( $\bar{M}_n = 4 \times 10^4$ ). (B. N. P. and R. G. Kitchen, unpublished observation).

terms in the viral expansion gain importance). The frictional properties of multicomponent macromolecular systems are less known. From some sedimentation and diffusion results<sup>4,5,9,12,14,16,24,26</sup> and general knowledge about binary systems one may conclude, however, that the frictional coefficient will increase markedly on addition of the second solute, but less so for intermediate concentrations than does the thermodynamic factor (see below).

Recent experiments<sup>17</sup> on the diffusion of one macromolecule (component 1) in dilute form in a solution containing increasing amounts of a second macromolecule (component 2) up to very high concentrations have revealed the following features. If component 1 is a compact globular particle (for example, bovine serum albumin (BSA)) diffusing in a solution containing dextran (component 2), a smooth decrease in  $D_{app}$  is observed (Fig. 1). These results are in agreement with earlier work<sup>9,14</sup>. However, if both solutes are chain polymers, then a marked difference in behaviour is observed (Fig. 2). In this case, the diffusion rate of polyvinylpyrrolidone (PVP) first decreases with increasing  $c_2$ ,

**Fig. 3** Variation in  $D_{app}$  of PVP ( $\bar{M}_n = 3.2 \times 10^5$ ) (component 1) as a function of  $c_2/c_2^*$  for various dextrans (component 2) of different molecular weight. ○, Dextran T 10 ( $MW = 1.0 \times 10^4$ ); □, Dextran T 20 ( $MW = 2.0 \times 10^4$ ); △, Dextran T 70 ( $MW = 7.0 \times 10^4$ ); +, Dextran T 150 ( $MW = 15.0 \times 10^4$ ).  $c_2^*$  is calculated using a modified version<sup>29</sup> of a relationship as given by Simha and Zakin<sup>28</sup>. (B. N. P. and G. Checkly, unpublished observations).

then increases markedly;  $D_{app}$  can reach very high values sometimes of the order of 45 times the value in the absence of component 2. Then  $D_{app}$  reaches a maximum and decreases at still higher values of  $c_2$ . These results point out the regulatory influence of the second solute on the diffusion rate of the first.

These results seem to be in accord with the general view of diffusion in multicomponent macromolecular systems as discussed above, with the following qualitative explanation. The diffusion rate is governed by an interplay between 'thermodynamic' and 'hydrodynamic' factors. Component 1 is present in high dilution and, up to a certain but fairly low value of  $c_2$ , the addition of component 2 mainly affects frictional properties and the diffusion rate of component 1 is lowered. When  $c_2$  has been raised sufficiently the thermodynamic interactions between the different macromolecules will, in the case of the linear polymers, rapidly become very strong due to large excluded volume effects and will dominate over the increase in friction. This explains the very steep increase in the  $D_{app}$  curve against  $c_2$ . Continued addition of component 2 finally gives a situation where close packing of the encompassed-volume-spheres of the solute molecules occurs. For dense hexagonal close packing, it has been suggested that this occurs at a concentration ( $c_2^0$ ) given by  $c_2^0 = 1.08/[\eta]$  where  $[\eta]$  is the intrinsic viscosity of solute 2 (ref. 28). At this concentration, there will be a drastic increase in the 'friction' which eventually will dominate over the thermodynamic interactions.

If the molecular weight and hence molecular domain of component 2 in the system studied in Fig. 2 is increased, then the resultant  $D_{app}$  against  $c_2$  curve is displaced to lower concentrations. However, if a normalised concentration scale is used,  $c_2/c_2^*$ , where  $c_2^*$  differs from  $c_2^0$  only by a small factor that allows for the compression of solute 2 (B. N. P. and A. G. Ogston, in preparation), then the curves  $D_{app}$  against  $c_2/c_2^*$  become superimposable (Fig. 3). It appears that the reduced scale defines approximately corresponding physical states for the

different molecular weight species. It is pertinent that the maximum value of  $D_{app}$  occurs at the point of incipient overlap of the molecular domains of component 2 (that is  $c_2/c_2^* = 1$ ).

That the molecular conformation of the diffusing species is critical in determining the diffusion features has been clearly demonstrated by study of the simultaneous diffusion of PVP and BSA in a concentrated solution of dextran. Whereas the diffusion transport of the chain polymer was enhanced by a factor of 12, that of albumin was reduced by a factor of 2 (unpublished observation).

This small note precludes a detailed theoretical examination of multicomponent diffusion and thermodynamic interaction but a number of features predicted by theory have been observed in the system discussed above. These include the marked dependence of  $D_{app}$  on: (1) molecular weight of component 1 (Fig. 2); (2) the concentration of both polymeric components; and (3) time.

Our observations may be relevant for understanding the rate and direction of diffusion in extracellular compartments containing high concentrations of, for example, polysaccharides or mucins. However, they may also be important for intracellular processes such as axonal flow.

## Ear ossicle of *Australopithecus robustus*

WE report here the discovery of the first ear ossicle, an incus, of a Plio–Pleistocene hominid. It is substantially different from that of modern man, and the dissimilarity exceeds that between the ear bones of *Homo sapiens* and of the African apes. The new incus is of interest particularly in view of the unique advantages that ear ossicles have for taxonomic and phylogenetic studies. (The only other fossil hominid ear ossicles are from Qafzeh<sup>1</sup> and are indistinguishable from those of modern man.)

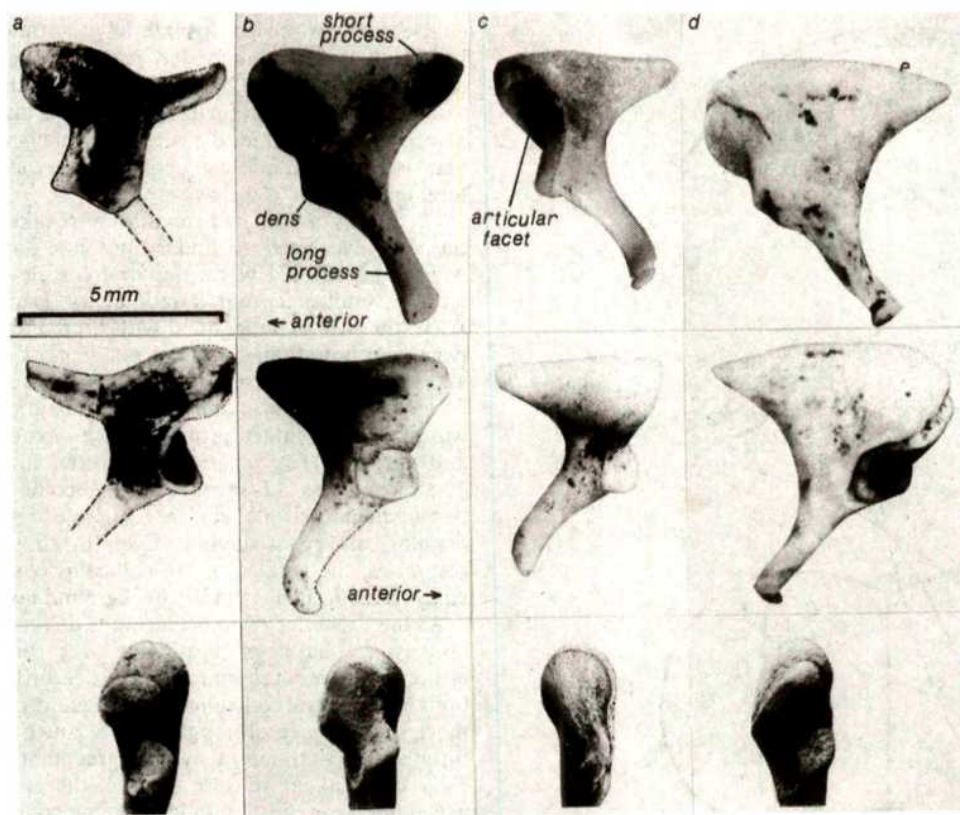

The right incus was discovered in the *Australopithecus robustus* specimen SK 848, a temporal bone from Swartkrans (a distinct genus, *Paranthropus*, is recognised by one of us, R.J.C.). The incus was found anatomically *in situ*—in the epitympanic recess—and is complete except for the long process (Fig. 1). The near-perfect state of preservation permits detailed examination of the bone's morphology, including the articular surface.

The body of the Swartkrans incus is inflated and bulb shaped. A deep indentation at the centre of the articular surface emphasises the protrusion of the oversized dens, thus providing the body with a somewhat more symmetrical appearance than in man, gorilla and chimpanzee. The short (posterior) process is cylindrical and of small diameter. The area of its attachment to the body is narrow compared with the corresponding area in man and the African apes, where the process is flat and broadens anteriorly to meet the body. In *A. robustus* the small diameter of the process results in a concave superior contour and the elevation of the body above the process.

Comparison of the articular surfaces also reveals profound differences. The synovial incudomalleolar joint in man is usually described as a saddle-shaped biaxial joint, and in this respect it resembles the chimpanzee and the gorilla. The saddle shape enables the superior part of the articular facet to be exposed in medial view (Fig. 1*b, c, d*, top) and the inferior part (on the dens) to be exposed in lateral view (Fig. 1*b, c, d*, middle). This twisting of the surface from the medial to the lateral sides of the bone is not found in *A. robustus*, where a view of the medial side does not include the articular surface (Fig. 1*a*, top). The two parts of the articular surface (superior and inferior) face each other, forming a more uniaxial joint shaped like the semilunar notch of the ulna. Only in *A. robustus* does the superior part of the articular surface occupy such a small portion of the bone's body (Fig. 1*a*, bottom).

Although the incus is tiny, its importance should not be overlooked. Furthermore, this is one of the most complete and undistorted bones of *A. robustus* yet discovered. The study of its morphology with respect to taxonomy and phylogeny is aided by additional advantages unique to this bone. It is fully formed at birth, and thus later changes are minimal. It has no muscles anchored on it and so exhibits none of the morphological effects often associated with muscular attachment. As Hershkovitz (ref. 2, p. 176) states in reference to the ear ossicles, "Their growth patterns, size, shape, position, and composition are not significantly influenced or modified by movements or stresses generated by the growth or remodeling of unrelated neighboring bones. In effect, ontogeny of the ossicle is virtually a complete and undisturbed expression of the basic controlling genetic factors. Importance of ear bone morphology and ontogeny in phylogenetic reconstructions cannot be underestimated." This is more true of the incus than the malleus<sup>3–5</sup>.

Specialisations of the ear are usually found in structures other than the ossicles, such as the pinna and the external auditory meatus, the tympanic bulla, the fenestra ovalis and the ligaments supporting the ossicles; specialisations are also exhibited by certain anatomical relationships, such as the proportion between the areas of the tympanic membrane and the fenestra ovalis<sup>3–5</sup>. Many of the modifications associated with the ear ossicles themselves are related to the position and orientation of

**Fig. 1** Comparison of the right incus of *A. robustus* (a) with that of modern man (b), chimpanzee (c) and gorilla (d). Top row, medial view of the bone; middle row, lateral view; bottom row, view of the articular surface. All bones are on the same scale and orientation.

these bones in the tympanic cavity and to the elongation of their processes<sup>3-5</sup>. Furthermore, the malleus—the most external ossicle in the chain—tends to be more specialised than the incus<sup>2-5</sup>. Only in cases of extreme modification of the ear, as in bats, moles and whales, is the morphology of the incus substantially affected<sup>3-5</sup>. It is interesting that the acute angulation of the articular facet's surface, which distinguishes the *A. robustus* incus from that of the African apes and man, is also characteristic of the rodent *Dipodomys merriami*, whose ear is specialised to an unusually low frequency range<sup>3</sup>. Furthermore, the extremely delicate short process in *A. robustus* (the site of attachment of the posterior ligament connecting the incus to the petrous bone) may indicate that, as in *D. merriami*, the ossicles were loosely suspended in the tympanic cavity<sup>3</sup>.

The solid appearance of the SK 848 incus and of its articular surface suggests that its shape is not the result of some pathological process. Its unusual morphology is far beyond the range of normal variation characteristic of the incudes of modern man and the great apes<sup>4</sup>. This is also supported by the observations made by one of us (Y.R.) on tens of *H. sapiens* bones from different populations and on five gorilla and 10 chimpanzee bones.

Although the specific phylogenetic and taxonomic implications of our findings are unclear because of the lack of a comparative fossil incus sample, this bone can provide at least a notion of how great a phylogenetic deviation is represented by the robust australopithecines.

We thank Dr E. Vrba for access to the Transvaal collection, Suellen Gauld for assistance with scanning electron microscopy, and F. C. Howell, T. White, L. Bruner and W. E. Meikle for helpful comments. This study was supported by grants from the Louis B. Leakey Foundation and the Boise Fund.

## Changes in the uncrossed retinotectal projection after removal of the other eye at birth

THE connections between the eyes and the brain are so arranged as to give an orderly representation in the brain, of the visual field. The mechanisms involved in this ordering have been extensively studied, particularly in the retinotectal pathway of submammalian vertebrates<sup>1-3</sup>. In these species the optic nerves decussate almost completely, retinal ganglion cells in one eye connecting only with the opposite tectum. In mammals, however, there is partial decussation at the optic chiasma, so that the superior colliculus receives optic fibres from both eyes. Binocular representation poses a problem for the ordering of retinotectal projections. If one point on the tectum is to correspond to only one point in visual space, seen through both eyes, the mapping rules onto the tectum must have opposing polarities in the two eyes, along the nasotemporal axis. This is shown in Fig. 1: a rostral movement in the colliculus corresponds

**Fig. 1** A schematic diagram showing the representation of the visual field on the retina and on the tectum of a mammal such as the hamster. The horizontal meridian of the visual field is depicted as an arrow and is shown projecting onto the two tecta so that the central field is found rostrally and the peripheral field caudally. There are connections from the temporal retina of both eyes to the rostral portion of each tectum such that one point on the tectum corresponds to only one position in the central visual field, seen through both eyes. It is apparent that the ordering of the projection shows opposing nasotemporal polarities in the ipsilateral and contralateral retinas. In left tectum the sequence G F E from the contralateral eye is matched by e f g in the ipsilateral eye; in the right tectum g f e is matched by E F G.

to a temporal movement on the contralateral retina but a nasal movement on the ipsilateral retina. Little is known about the factors determining the topography of the direct ipsilateral projection to the mammalian superior colliculus. Anatomical studies in rodents have shown that neonatal removal of one eye induces an increased projection from the remaining eye to the ipsilateral colliculus<sup>4,5</sup>. These aberrant uncrossed optic fibres are derived from all regions of the retina and apparently have a distribution appropriate for a normal contralateral projection, that is, the nasotemporal retinal axis is represented caudorostrally<sup>6</sup>. The only published physiological study investigating the topography (in enucleated rats) confirmed the anatomy as regards the nasotemporal axis but, surprisingly, found the dorsoventral axis reversed over most of the colliculus ipsilateral to the remaining eye<sup>7</sup>. Here I present results on the enucleated hamster showing that the colliculus ipsilateral to the remaining eye contains a double representation of the visual field displaying mirror-image polarity along the nasotemporal axis.

I have examined electrophysiologically the retinal representation in the superior colliculi of hamsters, *Mesocricetus auratus*, which had one eye removed at birth. I used both normally pigmented and albino strains in an attempt to distinguish the contributions to the retinotectal map of fibres which would normally have gone ipsilaterally, and of fibres induced by

enucleation, to project ipsilaterally. Normal albino mammals have only a small uncrossed retinal projection<sup>8</sup> and I have confirmed this for the hamster using both anatomical and physiological techniques (in preparation). This difference in the extent of the ipsilateral projection in pigmented and albino hamsters makes it interesting to compare the effects of contralateral enucleation in the two strains.

On the day of birth hamster pups were taken from the nest and the right eye removed under fluothane anaesthesia. Animals over 3 months old were prepared for electrophysiology in a manner similar to that described by Tiao and Blakemore<sup>9</sup>. Anaesthesia was maintained with urethane-chloralose (25 mg per kg per h urethane; 0.16 mg per kg per h chloralose) and the animals were paralysed with gallamine triethiodide (Flaxedil, 35 mg per kg per h). After removing the dura the visual cortex was usually left intact, protected by a mixture of liquid-paraffin and vaselife. The electrode (tungsten in glass<sup>10</sup>, tip length 12–18  $\mu$ m) was advanced into the colliculus approximately perpendicular to its surface; microlesions were made for histological reconstruction. Even in the absence of visual responses, the surface of the colliculus could be identified by characteristic changes in the background noise.

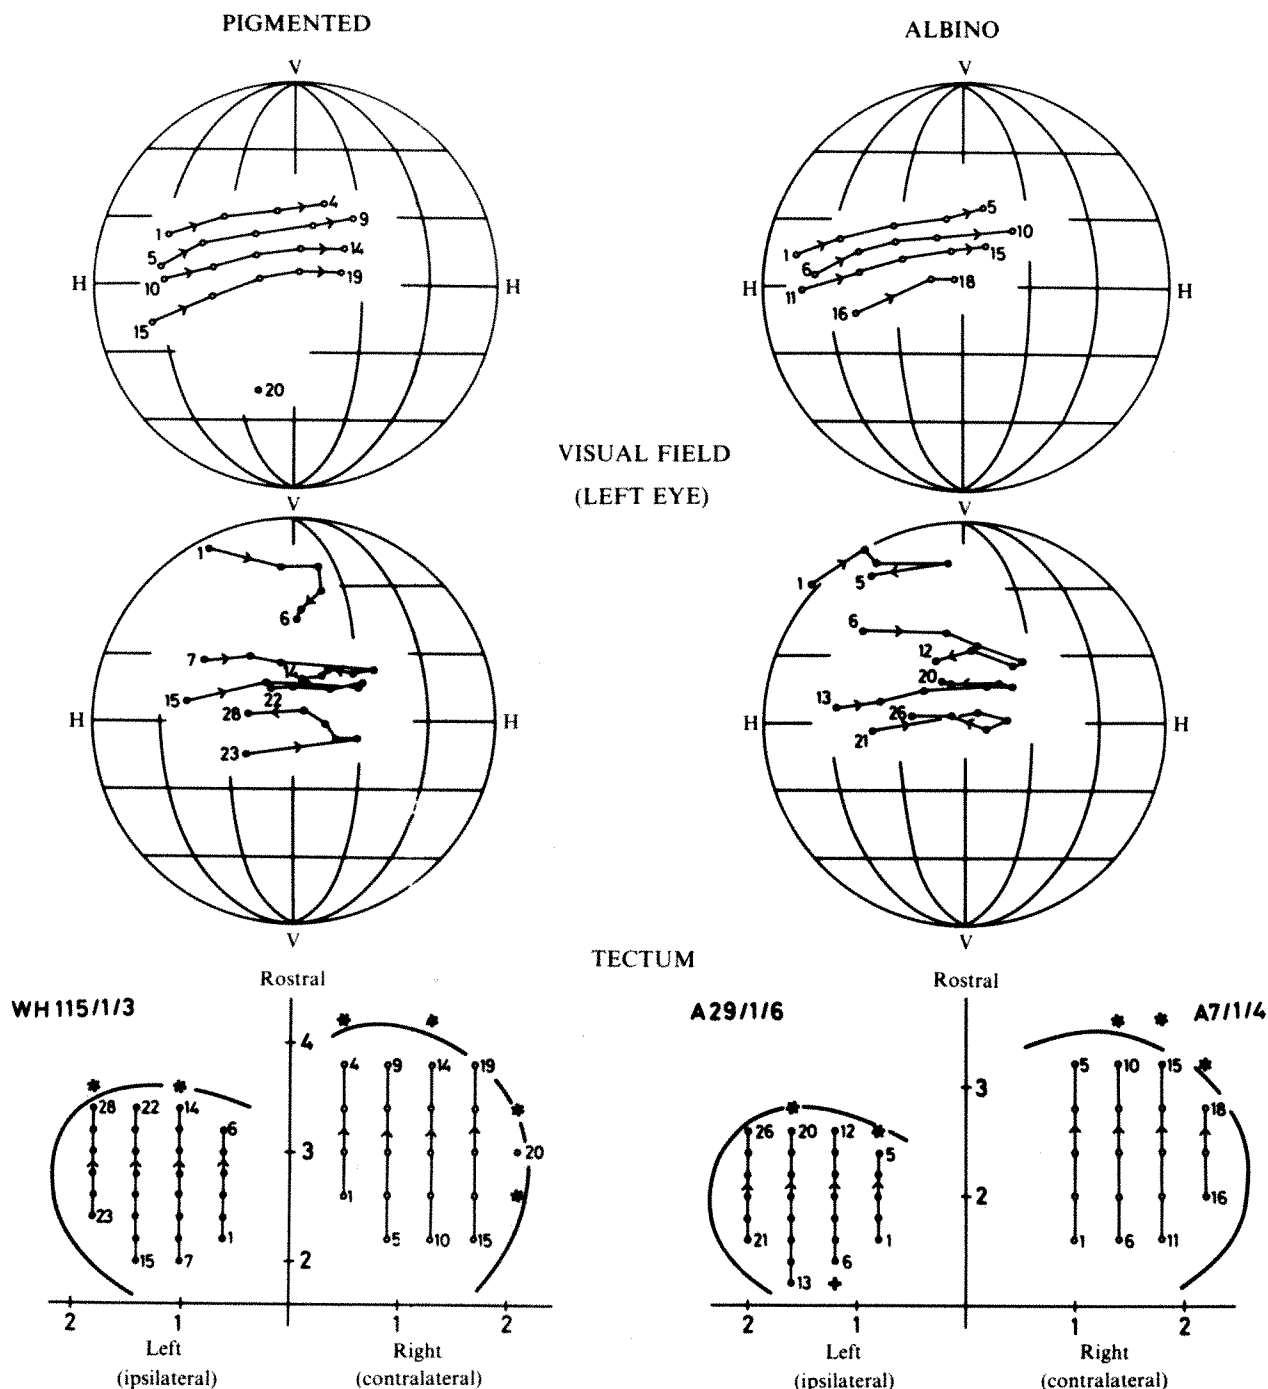

As the existence of collicular units driven through the ipsilateral eye<sup>11–13</sup> has been questioned<sup>14</sup>, recordings were first made in normal pigmented animals. Cells recorded during penetrations in the rostral colliculus were frequently responsive through the ipsilateral eye although usually much more weakly than through the contralateral eye, in agreement with the findings of Tiao and Blakemore<sup>11</sup>. In general, the part of the tectum in which there were ipsilaterally evoked responses agreed with the distribution of uncrossed optic terminals defined by anatomical methods (in preparation). In addition, receptive fields in the two eyes always shifted together in visual space as the electrode was moved across the colliculus. Consequently, the situation shown in Fig. 1 does represent that of the normal hamster.

Recordings were made in 12 enucleated animals (six albino and six normally pigmented): 299 penetrations into the mid-brain ipsilateral to the remaining eye and 50 in the opposite side (two animals). Multi-unit activity was recorded as soon as the electrode entered the colliculus and the receptive field was plotted by moving spots of light on a hemispherical screen in front of the animal. Receptive fields were generally 10–20° in diameter, occasionally much larger, but no double receptive fields were seen<sup>7</sup>. Compared with the visual responses from the ipsilateral eye in the normal animal, those in the enucleated animal were much brisker and were recorded over a far greater extent of tectum.

Figure 2 shows typical collicular maps of the visual field for animals enucleated at birth and recorded when adult. A comparison of the uncrossed and crossed projections in one animal (Fig. 2, WH 115/1/3) shows that there is a reversal within the retinotectal topography of the uncrossed projection. Whereas a caudorostral movement in the colliculus contralateral to the remaining eye gives a normal monotonic progression from temporal to nasal visual fields, such a movement in the ipsilateral colliculus corresponds initially to a temporonasal field progression, which then reverses to move from nasal to temporal fields. The polarity of the retinotopic map in the rostral tectum is appropriate for a normal ipsilateral projection whereas that in the caudal tectum is appropriate for a projection to the contralateral side.

This pattern of ipsilateral retinotectal topography following removal of one eye at birth, was seen in all 10 animals in which the mapping was sufficiently extensive. There is no obvious difference between pigmented and albino animals (Fig. 2). The retina maps continuously onto the tectum but with two polarities; consequently, parts of the retina are represented in two places on the tectum. It is only the central part of the visual field (temporal retina) that is mapped twice. As in the normal animal, the rostral colliculus represents only the central (normally binocular) visual field. The aberrant projection to the caudal colliculus includes both central and peripheral visual field and is

**Fig. 2** The mapping of the visual field, seen through the left eye, onto the superior colliculi, is shown for the pigmented hamster (left) and the albino (right). The right eye of each hamster had been removed on the day of birth. Filled circles indicate the locations of penetrations into the left colliculus (ipsilateral to the remaining eye) and also the position of the corresponding receptive fields in visual space; contralateral penetrations and the matching receptive fields are depicted by open circles. The electrode, which was angled 35° forward from the vertical in the parasagittal plane, was moved in a regular matrix of penetrations over a horizontal stereotaxic plane through lambda. The axes (in mm) at the bottom of the figure plot the intersections of the penetrations with this plane, the origin being the lambda. The points representing each parasagittal line of penetrations are joined and the progression from caudal to rostral tectum is indicated by the arrowheads. Asterisks denote penetrations falling outside the colliculus and the cross refers to one penetration within the colliculus on which no visual response could be elicited. Above the collicular representations are the visual field maps. In each case, the upper map (open circles) is derived from penetrations in the contralateral (right) colliculus and the lower (filled circles) from ipsilateral penetrations. The visual field coordinate system is that used by Tiao and Blakemore<sup>11</sup>, using axis-vertical coordinates for the hemisphere whose anterior pole lies directly in front of the animal. The meridians and parallels are shown at 30° intervals; H-H and V-V are the horizontal and vertical meridians. To compensate for divergence of the eyes under relaxant, a small correction was applied to the positions of the receptive fields, assuming that the normal projection of the optic disk (monitored with an ophthalmoscope) lies 54° from the vertical meridian and 25° above the horizontal meridian<sup>11</sup>.

consequently compressed compared with the normal crossed projection.

Thus, after removal of one eye at birth, the uncrossed fibres exhibit retinotectal mapping polarities appropriate for both contralateral and ipsilateral projections in the normal animal. This implies that the mechanisms involved in determining these polarities are independent of whether or not decussation occurs and that the map in the rostral colliculus, appropriate for a normal ipsilateral projection, does not require the presence of an intact projection from the opposite eye. A further surprising feature is the segregation of the two maps in the ipsilateral tectum. The aberrant input showing mapping rules appropriate to a contralateral projection might have been expected to fill the whole colliculus, with the two maps superimposed in the rostral half as they are in the normal animal (where they come from different eyes).

This segregation could arise if the aberrant axons, induced to project ipsilaterally by enucleation of the other eye but exhibiting contralateral mapping rules, arrive at the tectum much later than would a normal crossed projection and find themselves excluded from the rostral tectum because of proliferation of the normal ipsilateral termination in that region. However, this argument might predict that the area of rostral tectum occupied by a normal ipsilateral map should still be very small in the enucleated albino; surprisingly, it is not (Fig. 2). Thus, in albinos at least, some of the fibres that are induced to project ipsilaterally, nevertheless, behave appropriately for a normal ipsilateral projection; perhaps these are the fibres that the albino mutation would normally cause to pass contralaterally rather than ipsilaterally<sup>15-17</sup>.

An important question is whether the physiologically determined retinotectal map actually reflects the pattern of direct retinal ganglion cell input<sup>18,19</sup>. In this context further anatomical work is necessary to ascertain whether the apparent discrepancy between the maps found in this study and those determined anatomically in the rat<sup>6</sup> is real. A further complication is the existence in mammals of a projection from the visual cortex to the superior colliculus<sup>20,21</sup>, the removal of which, in the cat, decreases ipsilateral driving of tectal neurones<sup>22</sup>. Cunningham and Speas<sup>7</sup> removed the cortex before recording, but it is unlikely that this explains the disparity between their results and mine, as I found that removal of the visual cortex, in two animals, had no significant effect on the topography of the ipsilateral projection mapped before and after the lesion. The topography was also unaffected by subsequent removal of the colliculus contralateral to the remaining eye.

These findings imply that the normal direct projection from the eye to the ipsilateral tectum (occurring to a significant extent only in mammals) has an inherent mapping specificity which is independent of input from the other eye. The observation that two maps of different polarity, arising from one eye, can co-exist within a single tectum may mean that a single area of retina contains two populations of ganglion cells exhibiting opposed polarity labels. Alternatively, it could be that the caudal and rostral halves of the tectum provide different mapping cues for fibres entering from the ipsilateral eye. A further complication arises if uncrossed fibres in both normal and enucleated animals are branches of crossed fibres, as has been suggested for the rat<sup>23,24</sup>. In that case, the two branches of a single retinal ganglion cell would have to display different mapping rules according to their laterality. Further work is required to provide fundamental information about the formation of visual maps in the mammalian brain.

I thank Dr Colin Blakemore for advice and discussion. The work was supported by grants from the MRC.

## Blood platelets do not provide endoperoxides for vascular prostacyclin production

PROSTACYCLIN (PGI<sub>2</sub>), the most active natural inhibitor of blood platelet aggregation described so far, is synthesised from the cyclic endoperoxide, PGH<sub>2</sub>, derived from endogenous arachidonic acid by the cyclo-oxygenase enzyme system. Exogenous endoperoxides are also readily converted into PGI<sub>2</sub> (refs 1, 2). Indomethacin inhibits the cyclo-oxygenase activity and thereby prevents PGH<sub>2</sub> formation. Because of this lack of precursor, endogenous PGI<sub>2</sub> production of indomethacin-treated tissue does not occur. However, when vascular tissue, pretreated with indomethacin, is incubated in platelet-rich plasma (PRP), its PGI<sub>2</sub> production is restored. On the basis of this observation it has been suggested that activated blood platelets can be a source of exogenous endoperoxides, stimulating the vascular prostacyclin formation and, consequently, limiting the growth of a platelet thrombus<sup>3</sup>. We now report results indicating that it is highly unlikely that blood platelets are able to promote vascular prostacyclin formation by supplying cyclic endoperoxides.

Male Wistar rats, specific pathogen-free, mean body weight about 300 g, were bled under ether anaesthesia by puncturing the abdominal aorta. The blood was collected in sodium citrate (3.8 w/v % 1 part + 9 parts of blood) and PRP and platelet-poor plasma (PPP) were prepared by differential centrifugation. Aortas were removed, cleaned from adjacent tissue, opened longitudinally and kept in Krebs-Henseleit buffer with or without indomethacin (2 µg ml<sup>-1</sup>) for at least 60 min at 0°C. A small piece of tissue (diameter 3 mm, dry weight ~100 µg) was punched out of the aorta and incubated immediately in 200 µl of either PPP or PRP in a gently shaken plastic vial for 3 min at room temperature. Measurement of the prostacyclin content of the incubate was based on the inhibiting effect of the incubate on ADP-induced aggregation of blood platelets. Incubation of normal aortic tissue resulted in the production of an aggregation-inhibiting principle with typical prostacyclin characteristics<sup>4</sup>. No significant difference in PGI<sub>2</sub> production was observed on incubation with either PPP or PRP (Fig. 1).

Indomethacin-treated tissue did not produce prostacyclin, irrespective of whether it had been incubated in PPP or PRP (Fig. 1). Similar results were obtained with longer incubation times (up to 12 min) and/or using human PPP and PRP as incubation media. Prostacyclin formation of normal aortas was considerably stimulated and that of indomethacin-treated aortas completely restored when PGH<sub>2</sub> was added to the

**Fig. 1** Prostacyclin production of rat aortic tissue, some treated with indomethacin (aorta-into), on incubation (3 min) in platelet-poor rat plasma (PPP, platelet count  $8-10 \times 10^3 \mu\text{l}^{-1}$ ) or platelet-rich rat plasma (PRP, platelet count  $1.7 \times 10^6 \mu\text{l}^{-1}$ ) at room temperature. The incubate (see text) was centrifuged (45 s; Beckman 152 microfuge) and 1 min after termination of incubation 50  $\mu\text{l}$  was added (A) to an aggregometer cuvette (Born/Michel) containing 0.75 ml saline (0.85 w/v % NaCl, 7 parts +  $\text{CaCl}_2 4 \times 10^{-3} \text{ mol l}^{-1}$ , 1 part) and 0.1 ml rat PRP, which had been preincubated (37 °C) for 2.5 min. Thirty seconds after incubate addition 0.1 ml ADP was added (B) to a final concentration of  $2.5 \times 10^{-7} \text{ mol l}^{-1}$ . Aggregation is indicated by the % change in light transmission ( $\Delta T$ ). Prostacyclin content of the incubates was calculated from the difference in aggregation in the presence of aorta-containing incubates (b) compared with aorta-free incubates (a) and expressed as % inhibition:  $\text{Inh. \%} = (a - b/a)100\%$ . Mean values  $\pm$  s.e.m. of seven determinations.

incubation medium ( $1 \mu\text{g ml}^{-1}$  final concentration), thus showing the responsiveness of the tissue to exogenous precursor in the present experimental conditions. Therefore, it can be concluded that PRP, gently shaken at room temperature for 3 min, does not supply the vascular wall with endoperoxides for prostacyclin synthesis.

Because this PRP treatment might not have activated the platelets sufficiently to initiate arachidonate peroxidation, in the next series of experiments platelet endoperoxide production

**Fig. 2** Prostacyclin production of rat aortic tissue which had (aorta-into) or had not (aorta) been preincubated ( $\geq 60$  min) in indomethacin-containing Krebs-Henseleit buffer ( $2 \mu\text{g ml}^{-1}$ ). Aggregation of rat PRP (platelet count  $1.7 \times 10^6 \mu\text{l}^{-1}$ ) was triggered (A) by collagen ( $5.6 \times 10^{-6} \text{ g protein ml}^{-1}$  final concentration). At the beginning of aggregation (delay time  $\sim 60$  s) aortic tissue was added (B). Aggregation was quantified as the % change in transmission 3 min after adding the tissue ( $\Delta T$ ). Prostacyclin production was determined by measuring the difference in collagen-induced aggregation after tissue addition (b) compared with control aggregations without added tissue (a) and expressed as % inhibition:  $\text{Inh. \%} = (a - b/a)100\%$ . Mean values  $\pm$  s.e.m. of 16 determinations.

was triggered by collagen. PGI<sub>2</sub> formation by normal and indomethacin-treated aortic tissue was assessed on incubation in PRP during aggregation induced by a collagen dose that caused platelets to produce endoperoxides (measured as malondialdehyde) and to release part of their granule content<sup>5</sup>. The results (Fig. 2) show that indomethacin-treated aortic tissue is unable to produce prostacyclin even if it is incubated in a suspension of collagen-activated blood platelets.

We then investigated whether the prostacyclin production of vascular tissue not treated with indomethacin could be influenced by incubation in PRP producing different amounts of endoperoxides. For this, we used platelets and aortas of normal rats and animals deficient in essential fatty acids (EFA). Platelets of these latter animals, when triggered by collagen, aggregate less than normal platelets<sup>6,7</sup> and produce only small amounts of endoperoxides and thromboxanes<sup>5,7,8</sup>. Their vascular prostacyclin production is lower than that in normal animals<sup>4</sup>, but thromboxane<sup>7</sup> and prostacyclin synthetase<sup>4</sup> are present in normal amounts.

**Fig. 3** Effect of normal and indomethacin-treated aortic tissue on the % light transmission ( $T$ ) of PRP and ADP-induced aggregation in PRP. A PRP dilution (for details see legend to Fig. 1) was stirred (1,000 r.p.m.) in an aggregometer at 37 °C. After 3 min (A) a piece of aorta was added. Ten minutes later (B) the tissue was removed and ADP added to trigger aggregation. a, No aorta. Aggregation indicates response of platelets to ADP. b, Normal aorta. No platelet shape change and aggregation after either tissue addition or ADP administration. In later experiments this was shown to be the result of prostacyclin formation by the added tissue. c, Indomethacin-treated aorta. The immediate decrease in transmission and the diminishing oscillations indicate activation of the platelets by the vascular tissue. After some time the tracing tended to return to normal, indicating de-activation of the platelets. Together with the absence of aggregation on ADP addition, this suggests progressively increasing prostacyclin formation, which was confirmed in later experiments (not shown).

If platelet endoperoxides stimulate vascular prostacyclin formation, one would expect more PGI<sub>2</sub> to be formed on incubation of vascular tissue with collagen-activated normal than EFA-deficient PRP. However, Table 1 shows that neither normal nor EFA-deficient aortic tissue produce more PGI<sub>2</sub> on incubation with collagen-activated normal PRP than with collagen-activated EFA-deficient PRP.

Because normal as well as EFA-deficient vascular tissue can easily be stimulated to produce more PGI<sub>2</sub> merely by adding exogenous PGH<sub>2</sub> to the incubation medium, it is highly unlikely that activated blood platelets contribute to vascular prostacyclin synthesis by providing cyclic endoperoxides. As shown by Bunting *et al.*<sup>3</sup> and confirmed by others<sup>9,10</sup>, including ourselves (Fig. 3), indomethacin-treated tissue prevents aggregation when incubated in PRP. The mechanism for this is unknown, but we

**Table 1** Prostacyclin production of rat aortic tissue on incubation with collagen-aggregated PRP of normal or EFA-deficient rats

Aorta	PRP	Prostacyclin (ng PGE <sub>1</sub> per min)	Difference
Control	Control	9.1 ± 1.32	
Control	EFA-deficient	7.8 ± 0.91	$P > 0.10$
EFA-deficient	Control	1.3 ± 0.58	$P < 0.001$
EFA-deficient	EFA-deficient	1.4 ± 0.41	$P > 0.10$

For technical details see the legend to Fig. 2. As the collagen-induced aggregation is depressed in EFA deficiency<sup>6,7</sup>, effects were calibrated against the inhibitory effect of prostaglandin E<sub>1</sub> (PGE<sub>1</sub>). Dose-response curves of PGE<sub>1</sub> were made in both normal and EFA-deficient PRP. Prostacyclin production is given in PGE<sub>1</sub> equivalents (ng min<sup>-1</sup>), mean ± s.e.m. of 11 determinations. Results were statistically evaluated using the Kruskal-Wallis analysis of variance on ranked observations<sup>11</sup>.

believe that it is due to removal of indomethacin from the cyclo-oxygenase enzyme system, which is consequently reactivated during incubation. This was confirmed by the following experiment.

A piece of indomethacin-treated rat aorta was added to a stirred rat PRP dilution and the change in transmission recorded continuously. When after 10 min the tissue was removed and ADP (0.1 ml,  $2.5 \times 10^{-6}$  mol l<sup>-1</sup>) added to the PRP, no aggregation was observed (Fig. 3). Aggregation did occur, however, when the platelet mixture was stirred without added aorta (Fig. 3), confirming Bunting's observation that indomethacin-treated vascular tissue produces PGI<sub>2</sub>-like activity when incubated in stirred PRP.

The removed tissue was quickly rinsed in Krebs-Henseleit buffer, incubated in 200 µl Tris buffer (0.02 mol l<sup>-1</sup>, pH 7.2) at

**Fig. 4** Endogenous prostacyclin production (% inhibition of ADP-induced aggregation) of indomethacin-treated aortic tissue of rats after preincubation. Pieces of vascular tissue were added to an aggregometer cuvette containing 0.8 ml saline + CaCl<sub>2</sub> (see Fig. 1) and 0.1 ml PRP, PPP or Krebs-Henseleit buffer. This mixture had been preincubated for 3 min at 37°C, while stirred at 1,000 r.p.m. After 10 min the tissue was removed, rinsed in Krebs-Henseleit buffer and incubated in 200 µl Tris buffer (0.02 mol l<sup>-1</sup>, pH 7.2) at room temperature in a gently shaken vial. After 3, 10 and 20 min 50-µl portions of the incubate were assessed for their PGI<sub>2</sub>-like activity on the basis of their inhibiting effect on ADP-induced aggregation (see Fig. 1). Results are means ± s.e.m. of seven determinations. First and second media were, respectively: ■, PRP, Tris; □, PPP, Tris; ○, Krebs-Henseleit, Tris; ●, Krebs-Henseleit + indomethacin (2 µg ml<sup>-1</sup> final concentration), Tris + indomethacin (2 µg ml<sup>-1</sup>).

room temperature, and endogenous PGI<sub>2</sub> production assessed in 50-µl portions of the incubate taken after 3, 10 and 20 min of incubation. If the cyclo-oxygenase was still blocked by indomethacin, no prostacyclin production would be expected. However, substantial amounts of endogenous PGI<sub>2</sub>-like activity were detected in the incubate (Fig. 4). This is not due to 'late' conversion of stored, platelet-derived PGH<sub>2</sub>, as essentially similar results were obtained on 10 min incubation of indomethacin-treated tissue in a stirred PPP dilution or in a dilution of Krebs-Henseleit buffer (Fig. 4). Endogenous PGI<sub>2</sub> production could be prevented only when the first as well as the second incubation was carried out in a saline milieu, containing indomethacin (Fig. 4).

Indomethacin added to PRP or PPP (2 µg ml<sup>-1</sup>) did not prevent reactivation of vascular cyclo-oxygenase (not shown), most probably because the added indomethacin is bound to plasma proteins, resulting in too low a 'free' indomethacin concentration. There was no appreciable difference between the use of PRP or PPP during the first incubation on subsequent endogenous PGI<sub>2</sub> production by the tissue. This indicates that platelets do not have a special effect on reactivation of vessel wall cyclo-oxygenase. In this respect, plasma seems superior to buffer, probably because the strong affinity of indomethacin for plasma proteins facilitates its removal from vascular cyclo-oxygenase.

In our first experiment (Fig. 1), we were unable to detect PGI<sub>2</sub> production by indomethacin-treated aortas incubated in PRP or PPP. Obviously, the incubation conditions in our last experiment (temperature 37°C instead of room temperature; time 10 instead of 3 min; plasma mixing by stirring instead of shaking) enhanced the removal of indomethacin from vessel wall cyclo-oxygenase.

Later experiments, to be presented elsewhere, showed that reactivation of indomethacin-blocked vascular cyclo-oxygenase needs about 6 min of incubation in plasma at 37°C, stirred at 1,000 r.p.m. The presence of platelets during this incubation had no significant effect.

Thus, we have shown that in a variety of conditions blood platelets do not enhance vascular prostacyclin production by supplying cyclic endoperoxides. Experiments suggestive of the existence of such a pathway did not take into account that the binding of indomethacin to cyclo-oxygenase, and consequently, the cyclo-oxygenase inactivation is reversible and can easily be overcome by incubation of indomethacin-treated tissue in an indomethacin-free medium.

*Note added in proof:* Recently, Needleman *et al.*<sup>12</sup> reached a similar conclusion, namely that in normal conditions blood vessels do not use platelet cyclic endoperoxides for prostacyclin synthesis.

## Is alanine the active component in anterior pituitary extracts proposed to contain a thymotropic factor?

SAXENA AND TALWAR have reported the occurrence of a factor in extracts of the anterior pituitary which stimulates thymidine incorporation into thymocytes *in vitro*<sup>1</sup>. The possible existence of a previously unknown thymotropic pituitary factor was discussed. The test system used by Saxena and Talwar consisted of isolated rat thymocytes cultured in a defined glucose salt medium without serum or other additives. Anterior pituitary extract (APE) was added and the uptake of <sup>3</sup>H-thymidine into acid-insoluble material during short-term incubation was greatly stimulated. It was briefly mentioned that stimulation was also obtained when thymocytes were cultured in RPMI or Parker 199 medium. No effect was observed on tissue slices from liver, heart, kidney and diaphragm. The factor was said to have a molecular weight of 500 and an isoelectric point of 7.9, but the methods of determining these properties were not described. We report here on the isolation of an active component in the APE and its identification as the amino acid alanine. APE was tested for the ability to stimulate thymidine incorporation and mitotic activity in guinea pig thymocytes in our *in vitro* systems (test systems are described in the legends to Table 1 and Fig. 1). The incorporation of thymidine and the mitotic activity were both stimulated in our experiments (Fig. 1a). The stimulatory effect on thymidine incorporation was dose dependent and varied between 129 and 156% in different experiments.

APE was purified using preparative thin layer chromatography (TLC). In the first system (cellulose; ethanol 95%: ammonium acetate 1 M, pH 5.0; 7:3), at least 10 separate ninhydrin-positive bands were obtained. Fractions were eluted according to the ninhydrin stain and tested for the ability to stimulate thymidine incorporation. Active material was rechromatographed in other solvent systems, fractionated and again tested for activity. A fraction which was considered homogeneous was on analytical TLC found to correspond to the amino acid alanine. When alanine was used as a reference in the preparative runs, all the activity was found in the region of this amino acid. (Amino acids mentioned are in the L form unless indicated otherwise.)

The RPMI 1640 medium, used by us and many others for lymphoid cell cultures, contains all common amino acids except alanine and cysteine<sup>2</sup>. It has recently been discovered that alanine, when added to RPMI 1640 medium, causes a quantitatively important increase in the thymidine incorporation into thymocytes and lymphocytes of different organs and species<sup>3</sup>. Isolated rat liver cells are not stimulated by alanine (O.S., unpublished results). The addition of alanine also increases the frequency of mitoses in cultures of guinea pig thymocytes (Fig. 1b and ref. 4). The stimulatory effect of alanine in RPMI 1640 medium is detected at a concentration of 10  $\mu$ M and is maximal at 100  $\mu$ M. Concentrations up to 2 mM cause the same maximal stimulation. D-Alanine or  $\beta$ -alanine do not stimulate thymidine incorporation. Alanine is one of the most common amino acids in serum<sup>5</sup> and the alanine requirement would probably be provided for by the addition of serum to the culture medium. However, uncontrolled factors such as general enzyme inhibitors and uncharacterised growth factors present in serum render its use unsuitable in studies of lymphoid growth factors.

Lymphoid cells from different species seem to vary in sensitivity to alanine stimulation. In guinea pigs, for example, thymocytes are stimulated by less than 200%, whereas human thymocytes could be stimulated by more than 350% in RPMI 1640 medium (O.S., unpublished results).

Saxena and Talwar<sup>1</sup> used a defined glucose salt medium for their thymocyte cultures. We studied the effect of supplementing such a medium with nutrients, such as amino acids and vitamins. Table 1 compares the radioactivity incorporated into

thymocytes cultured in RPMI 1640 medium, in RPMI 1640 supplemented with alanine, and in Hank's-Dulbecco (H-D) medium (a mixture of equal parts of Hank's balanced salt solution and Dulbecco's phosphate-buffered saline, the compositions of which are described in ref. 2). The highest incorporation is found in the alanine-supplemented RPMI 1640 medium and the lowest in the H-D medium. Table 1 also shows the effect of addition of APE or alanine to the different media. When APE was tested for activity in alanine-supplemented RPMI 1640 medium, no stimulation of the thymidine incorporation was obtained. Thus, the stimulatory effect of APE in the RPMI 1640 medium depends on its alanine content. Material in extracts from bovine liver, spleen and thymus, which stimulated the thymidine incorporation into lymphocytes from various sources, has earlier been identified as alanine<sup>3</sup>. As shown in Table 1, addition of alanine is without stimulatory effect on thymidine incorporation in the H-D medium, indicating that the stimulatory effect of APE in this medium depends on alanine in combination with other amino acids, probably present in the extract. (Crude low molecular weight material (<10,000 daltons) from bovine thymus stimulates thymidine incorporation into guinea pig thymocytes cultured in H-D medium (O.S., unpublished data). Even highly purified low molecular weight material from tissue extracts (thymus, spleen and liver) contains, in addition to alanine, various amounts of other amino acids (K. Nordlind, personal communication).

We conclude that the stimulatory effect of APE on thymidine incorporation and the frequency of mitoses in RPMI 1640

**Fig. 1** Effects of APE (a) and alanine (b) on incorporation of <sup>3</sup>H-thymidine and frequency of colcemid-arrested metaphases in cultured thymus cells. The method for determination of <sup>3</sup>H-thymidine incorporation is described in the legend to Table 1. For quantification of mitotic activity, 1-ml cultures with  $5 \times 10^6$  cells were incubated in RPMI 1640 medium at 37°C. After 30 min, APE (1:2; see Table 1) or alanine (to make 0.65 mM) was added (time 0) in a volume of 0.2 ml. The procedure for preparation of the cells for mitotic counts is described elsewhere<sup>4</sup>. Briefly, cells were swelled on glass slides by hypotonic treatment, fixed by addition of methanol:acetic acid (3:1) and stained; 5,000 cells from each group were examined at  $\times 1,000$  magnification. Incorporation of <sup>3</sup>H-thymidine (c.p.m.) in 1 h is shown by vertical bars, and mitotic activity (% metaphases) by continuous (APE or alanine) and dashed lines (controls). Each point on the curves represents the frequency of cells in metaphase after a 2-h pulse with colcemid (100  $\mu$ l added to make 0.08  $\mu$ g ml<sup>-1</sup>). The values for <sup>3</sup>H-thymidine incorporation and mitotic activity after addition of APE (but not alanine) were measured at the same time using cells from the same suspension in both cases.

**Table 1** Thymidine incorporation into guinea pig thymocytes cultured in different media, and the effect of addition of APE or alanine

Addition	Incorporated radioactivity (c.p.m., mean of duplicate cultures)		
	RPMI 1640	RPMI 1640 + alanine (0.5 mM)	Hanks-Dulbecco
Control (sterile water)	7,602	12,446	4,033
Alanine (50 nmol per culture)	11,712 (154)	12,538 (101)	3,206 (79)
APE 1:2	10,381 (137)	10,274 (83)	5,530 (137)
1:4	9,905 (131)	11,114 (89)	5,294 (131)
1:6	8,505 (112)	10,861 (87)	4,771 (118)

$5 \times 10^5$  guinea pig thymocytes were incubated in 0.1-ml samples of the media indicated above. Incubations were carried out in a Linbro micro-titration plate in  $37^\circ\text{C}$  in an atmosphere of 10%  $\text{CO}_2$  in air. Penicillin ( $100 \text{ IU ml}^{-1}$ ) and streptomycin ( $100 \mu\text{g ml}^{-1}$ ) were added to all media and glutamine (2 mM) was added to the RPMI media before the onset of cultures. One ampulla of lyophilised APE was dissolved in 5 ml sterile water (according to instructions from R. K. Saxena) and diluted as indicated above; 10  $\mu\text{l}$  of APE or alanine was added to duplicate cultures from the start. Control cultures received 10  $\mu\text{l}$  of sterile water. Tritiated thymidine (0.5  $\mu\text{Ci}$ , 1  $\mu\text{M}$ ) in 10  $\mu\text{l}$  physiological saline was added after 4 h. One hour later the cultures were collected on a Skatron multiple cell collector using glass fibre filters. Incorporated radioactivity was measured in a Packard liquid scintillation spectrometer. Values in parentheses show the percentage of incorporation in the different media after the addition of alanine or APE compared with the control cultures.

medium are due to the presence of alanine in the APE. The effect of APE in glucose salt medium, shown by Saxena and Talwar, is probably caused by the presence of several essential nutrients in the APE, for example, a mixture of amino acids. As shown here, the growth of thymic cells (and probably other cells also) in short-term cultures is very dependent on the presence of essential nutrients. When culturing lymphoid cells, alanine should be included in the culture medium.

Due to the facts presented above, we feel that the existence of a new thymotrophic pituitary factor is not yet fully confirmed.

This work was supported by Karolinska Institutet. We thank Dr R. K. Saxena for his kind cooperation and gift of APE.

## Amputation of a suppressor determinant on lysozyme reveals underlying T-cell reactivity to other determinants

THE response to several thymus-dependent antigens is influenced by immune response (*Ir*) genes, usually those of the major histocompatibility complex. However, the relevant gene products and their cellular sites of action have not been fully characterised. It is evident that in certain cases, the *Ir* genes can

function to select those determinants which will be presented to activate T cells. This control operates, at least in part, at the level of macrophage-T-cell interactions. We have previously proposed<sup>1</sup> that the failure of a T-cell response in H-2<sup>b</sup> mice following immunisation with chicken lysozyme (HEL) could be due to preferential stimulation of suppressor T cells. A suppressor mechanism which nullifies the activity of lysozyme-specific T-helper cells has been reported from our laboratory<sup>2</sup>. Comparison of the amino acid sequence of various closely related lysozymes reveals that molecules which have tyrosine at position 3 are immunogenic in H-2<sup>b</sup> mice whereas lysozymes with phenylalanine at position 3 are non-immunogenic in such strains<sup>3</sup>. We have considered the possibility that the latter lysozymes possess a determinant that preferentially stimulates suppressor cells in H-2<sup>b</sup> mice, whereas the former lack this 'suppressor determinant'. Other studies<sup>4-6</sup>, including those by Schwartz *et al.*<sup>7</sup> and Turkin and E.E.S.<sup>8</sup>, support a phenomenon of generalised suppression caused by restricted determinants. Here, we demonstrate that a strain which is unresponsive to HEL and whose T-cell proliferative activity is absent following immunisation with the entire molecule, possesses the potential to generate a vigorous T-cell response directed against a large fragment of the antigen. Suppressor cells directed against a restricted determinant on the molecule obscure this competence to respond to the majority of the molecule.

As a first test of the proposition that HEL carries a suppressor determinant, a major peptide of HEL lacking the putative

**Fig. 1** Groups of 10 C57BL/10 (a) and 10 C57BL/10.A (b) mice were injected with either 15  $\mu\text{g}$  of RCM-L<sub>11</sub> or 22  $\mu\text{g}$  RCM-HEL, emulsified in complete Freund's adjuvant (containing *Mycobacterium tuberculosis* strain H37Ra), divided in the hind footpads. Four weeks later, peritoneal exudate T-enriched lymphocytes (PETLES) were prepared as described by Schwartz *et al.*<sup>10</sup>. Five days after injection of 1 ml of 10% thioglycollate, the peritoneal cells were recovered, washed and passed over nylon wool to enrich for T cells<sup>11</sup>.  $2 \times 10^5$  PETLES per well were stimulated in round-bottomed microtitre plates (Microbiological Associates) with medium alone (modified Eagle-Hanks' medium containing fresh L-glutamine, 2-mercaptoethanol, antibiotics and 10% heat-inactivated fetal bovine serum), or supplemented with 50  $\mu\text{g ml}^{-1}$  purified protein derivative (PPD), or antigens (4-200  $\mu\text{g ml}^{-1}$ ). Cultures were incubated at  $37^\circ\text{C}$  in 2%  $\text{CO}_2$ , 98% air for 5 d. Four days after initiation, cultures were pulsed with 1  $\mu\text{Ci}$  of [Methyl-<sup>3</sup>H]thymidine (specific activity 6.7 Ci mmol<sup>-1</sup>, NEN) in 10  $\mu\text{l}$  phosphate-buffered saline. The amount of antigen-stimulated incorporation of label into cellular DNA was determined by counting the cells collected 16 h later on filter disks in a liquid scintillation counter. The maximum stimulation observed in three separate experiments has been plotted as a relative per cent of the response stimulated by PPD (purified protein derivative of the same strain of *M. tuberculosis*). PPD stimulation ranged from 25-50,000 c.p.m. in different experiments; the background (medium alone) was 500-2,000 c.p.m. The bars represent mean incorporation  $\pm$ s.e.m. The antigen used in culture was either RCM-L<sub>11</sub> (▨) or RCM-HEL (■).

**Fig. 2** Using an identical protocol to that described in the legend to Fig. 1, groups of B10 mice were primed with 15  $\mu$ g RCM-L<sub>II</sub> or 22  $\mu$ g RCM-HEL, and the PETLES were isolated 4 weeks later. The individual or mixed PETLES populations were stimulated as shown, with 50  $\mu$ g ml<sup>-1</sup> RCM-L<sub>II</sub> or 75  $\mu$ g ml<sup>-1</sup> RCM-HEL. Mixtures of 2%, 20% or 50% RCM-HEL-primed PETLES with RCM-L<sub>II</sub>-primed PETLES were used, resulting in 22, 10 and 25% of the RCM-L<sub>II</sub>-induced level of incorporation, respectively. A representative experiment is shown, in which only the 20% mixture results are plotted.

suppressor determinant was used to prime B10 and B10.A congenic mice, and the *in vitro* proliferative potential of these peptide-primed T cells was determined. The peptide used was the reduced and carboxymethylated, cyanogen-bromide peptide RCM-L<sub>II</sub> (amino acid residues 13–105). This is the largest peptide derivable from HEL which lacks the presumptively suppressive region around the N-terminus. As this peptide was obtained from RCM-HEL, one underlying assumption that had to be tested was that the T-cell cross-reactivity observed between HEL and RCM-HEL<sup>9</sup> extended to the suppressor cell level. Therefore, groups of B10 and B10.A mice were immunised with intact RCM-HEL and the proliferative responses of T cells from these mice were determined in the peritoneal exudate T-enriched lymphocyte (PETLES) system first developed by Schwartz *et al.*<sup>10</sup>. Whereas RCM-HEL induced a vigorous PETLES proliferative activity in the B10.A strain, there was no response to RCM-HEL by B10 PETLES. We then tested the prediction that B10 mice should be capable of responding to RCM-HEL following 'amputation' of the suppressor-inducing determinant. B10 and B10.A mice were immunised with 15  $\mu$ g of RCM-L<sub>II</sub> (a molar equivalent of the standard dose of intact RCM-HEL) in complete Freund's adjuvant. Three to six weeks later, PETLES were prepared and the proliferative response of these cells was determined. As shown in Fig. 1, both B10 and B10.A PETLES from mice primed with RCM-L<sub>II</sub> demonstrate active proliferative responses to this large peptide. Furthermore, the stimulatory determinants recognised on RCM-L<sub>II</sub> are also available on intact RCM-HEL, as shown by the high degree of cross-stimulation of RCM-L<sub>II</sub>-primed PETLES in the B10.A case. In contrast, the distinct preference for RCM-L<sub>II</sub> by B10 PETLES may reflect the effect of primary suppressor T-cell recognition of the suppressor determinant on intact RCM-HEL.

The functional inability of RCM-HEL-primed B10 PETLES to proliferate in the presence of strong responsiveness to determinants on RCM-L<sub>II</sub> can be attributed to a suppressor-inducing determinant present on RCM-HEL, but absent from RCM-L<sub>II</sub>. Taken together, the regions absent from RCM-L<sub>II</sub> (residues 1–12 and 106–120) represent a determinant region very similar to the N–C disulphide peptide. This peptide has previously been shown to induce HEL-specific suppressor cells in B10 mice<sup>1</sup>. The combined evidence supports the concept that there is a population of precursor T cells available in B10 mice which can be effectively stimulated by determinants on RCM-L<sub>II</sub>.

The implication that RCM-HEL is able to raise suppressor T cells which can affect the proliferative response to RCM-L<sub>II</sub> was then tested directly in the experiment shown in Fig. 2. RCM-L<sub>II</sub>-primed PETLES, when stimulated by homologous peptide in culture, gave a proliferative response that was 55% of the value induced by purified protein derivative (PPD). RCM-HEL-primed PETLES again showed no proliferation *in vitro*, when stimulated by either RCM-HEL or RCM-L<sub>II</sub>, suggesting that no expansion of RCM-L<sub>II</sub>-specific T cells had occurred. These putatively suppressive cells were then titrated into the responsive, RCM-L<sub>II</sub>-primed population. As shown in Fig. 2, 20% of the RCM-HEL-primed PETLES completely obliterate the specific response; actually, this was true even when the proportion of suppressive cells was only 2%. It is particularly interesting that the suppression only occurred over an antigenic bridge which linked the suppressor determinant with the proliferation-inducing determinant. Thus, when suppressor cells were present and potentially fully active, RCM-L<sub>II</sub> added in culture stimulated a response similar to that seen in the absence of suppressor T cells. However, with RCM-HEL as antigen, suppression was easily demonstrable. This dominant suppressive effect obviated the possibility that for some reason, RCM-HEL was catabolised too quickly in B10 mice to make an impression on the immune machinery.

This reasonably active suppression on a primed T-cell proliferative response has previously been difficult to observe. It suggests that the most suitable system in which to detect suppression may be one, as above, in which the antigen (fragment) stimulating the target response, here RCM-L<sub>II</sub>, does not itself act on suppressor cells.

We conclude that many situations arise in systems under obvious genetic control<sup>2,7</sup>, but also with more complex antigens, where a particular haplotype will regard a determinant region as suppressive. The existence of this recognition will then obscure an underlying, vigorous responsiveness directed against other parts of the molecule.

One, if not the major role, of *Ir* genes may be performed by antigen-presenting cells (macrophages) in selecting the appropriate determinant to be offered to different subpopulations of T cells<sup>12,13</sup>. Although this has widely been considered as a problem relating to the activation of helper cells, our results indicate that suppressor cell triggering is the critical factor for the outcome of the total response. Whether antigen presentation to suppressor cell precursors is a macrophage function remains to be established. Our work suggests that what occurs is the presentation of different determinants to the competing subpopulations of regulatory T cells.

This work was supported in part by USPHS grants CA-24442 and AI-11183, and NCI contract CB-43972. We thank Dr Ronald Schwartz for generous help with the PETLES assay, and Julie Zackrisson for secretarial assistance.

## Solubilisation of high-affinity dopamine receptors

NEUROLEPTIC drugs are thought to act by blocking brain dopamine receptors<sup>1</sup>. *In vitro* binding assays using either <sup>3</sup>H-haloperidol<sup>2,3</sup> or <sup>3</sup>H-spiperone<sup>4,5</sup> have provided more direct evidence of this interaction. Although spiperone has been reported to label serotonergic receptors in the frontal cortex<sup>6</sup>, in the rat striatum, in both *in vitro*<sup>4-9</sup> and *in vivo* conditions<sup>5,10,11</sup>, the binding characteristics of this drug are dopaminergic. Initial attempts to solubilise the neuroleptic receptor were recently undertaken in our laboratory, but the <sup>3</sup>H-spiperone macromolecular complex obtained from rat striatal membranes after digitonin treatment<sup>12</sup> did not show the original high-affinity binding characteristics for dopamine agonists and antagonists except for spiperone itself. More recently, solubilised neuroleptic sites were found in digitonin extracts from calf caudate but they were still not characterised<sup>13</sup>. We now report the solubilisation of binding sites from dog striatum which retain the characteristics of membrane-bound dopamine receptors.

Mongrel dogs were anaesthetised with pentobarbital and Wistar rats were decapitated; their brains were removed and the striatum, cerebellum and frontal cortex were dissected out and homogenised in 0.25 M sucrose. A microsomal (P) fraction was prepared as previously described<sup>4</sup>. This membrane preparation was treated at 0 °C for 15 min with 1% digitonin suspended in 2 or 4 volumes of 0.25 M sucrose containing 10 mM sodium phosphate buffer (pH 7.2) and 0.01% NaN<sub>3</sub>. After centrifugation at 120,000 g (*r*<sub>av</sub>) for 60 min in a SW 65 Ti Spinco rotor, the supernatant, which was considered as the soluble preparation (~2 mg protein ml<sup>-1</sup>), was removed very carefully without disturbing the pellet. An aliquot of this solubilised preparation was incubated at 0 °C for 16 h in the presence of  $2 \times 10^{-9}$  M <sup>3</sup>H-spiperone (specific activity 23.6 Ci mmol<sup>-1</sup>, NEN) and various concentrations of unlabelled drugs. Aliquots of 0.1 ml of the incubation mixture were layered on the top of a Sephadex G-50 Medium column (13 × 0.5 cm). Elution was carried out at 2 °C with 10 mM sodium phosphate (pH 7.2) containing 0.01% NaN<sub>3</sub>. Four-drop fractions were collected in scintillation

**Fig. 1** Inhibitory effect of (+)butaclamol (●—●) and (–)butaclamol (○—○) on the binding of <sup>3</sup>H-spiperone to solubilised material from dog striatum. Control experiments with (+)butaclamol used cerebellum extract (▲—▲) and thermally inactivated (56 °C for 10 min) preparations from dog striatum (○—○) and cerebellum (▲—▲). The values given are from one typical experiment.

vials and then counted for radioactivity. The gel-filtration procedure enabled the bound <sup>3</sup>H-spiperone macromolecular complex to be separated from the free drug, as described in more detail previously<sup>12,14</sup>.

Figure 1 shows that the <sup>3</sup>H-spiperone binding in the solubilised preparation from dog striatum revealed a very pronounced stereospecific effect; (+)butaclamol competed with the binding at a concentration 300 times lower than (–)butaclamol, the inactive enantiomer. The inhibitory effect of

Inhibition was measured at five different concentrations and expressed as the IC<sub>50</sub> value (the drug concentration causing 50% inhibition of the stereospecific <sup>3</sup>H-spiperone binding). The blank values were obtained using  $2 \times 10^{-6}$  M (+)butaclamol<sup>4</sup> except for the soluble preparation of rat striatum where the heat-inactivated preparation was used as blank<sup>12</sup>.

\*For spiperone, (+)butaclamol, haloperidol, flupenthixol, fentanyl and mianserin, the IC<sub>50</sub> values in solubilised dog striatum preparations are the mean values to two to five different experiments. This was also the case for the spiperone, benperidol, (+)butaclamol and (–)butaclamol IC<sub>50</sub> values in solubilised preparations from rats.

†Most of the values were taken from refs 4 and 6.

(+)-butaclamol was not observed when a cerebellum extract or a thermally inactivated preparation from striatum and cerebellum was used. The stereospecificity of the solubilised binding sites is quite comparable to that found in the membrane preparations from rat<sup>4,7-9</sup> and dog striatum (Table 1). When compared with membrane fractions, the solubilised preparation from dog striatum was more rapidly inactivated by heat<sup>15</sup>. Table 1 shows that various dopamine antagonists belonging to different chemical classes (butyrophenone, phenothiazine, diphenylbutylamine, thioxanthene, procainamide and benzoquinolizine) and dopamine agonists (tetraline derivative<sup>6</sup> and lysuride<sup>16</sup>) were nearly all of similar activity in soluble and membrane preparations from dog striatum (correlation coefficient  $r = 0.94$ ), whereas anticholinergic, analgesic, a  $\beta$ -blocking agent, a minor tranquilliser and serotonin antagonists were practically inactive. Of the neuroleptic drugs, only chlorpromazine was relatively less active in the solubilised preparation, presumably because of its high affinity for nonspecific binding sites<sup>17-19</sup>.

In contrast to this, the  $IC_{50}$  values obtained using a solubilised preparation from rat striatum differed markedly from that obtained in membrane preparations. For example, benperidol displayed a 3,800-fold difference between the  $IC_{50}$  values of soluble and membrane preparations in rat striatum and only a twofold difference in the dog. Note that the affinities of dopamine antagonists and agonists are quite similar in membrane preparations of dog and rat. Interestingly, R 5260 (compound 25 of ref. 20), which is an analgesic ( $IC_{50}$  of fentanyl binding  $1.0 \times 10^{-9}$  M), was more active in inhibiting  $^3H$ -spiperone binding in the rat striatum soluble preparation than potent neuroleptic drugs like haloperidol and benperidol. Therefore, the binding sites solubilised from rat striatum displayed only a high affinity for spiperone or derivatives related to the spiro moiety (R 5260 and also compounds 2, 3, 4 of ref. 20). We assume that such binding sites correspond to the non-stereospecific displaceable sites detected in rat striatum using  $^3H$ -spiperone as ligand<sup>21</sup>.

As shown in Fig. 2, a good correlation between the spiperone binding in solubilised preparations and the antagonism of apomorphine-induced emesis was found for the dog striatum ( $r = 0.89$ ) but not for the rat striatum. Spiperone was the only drug equiactive in solubilised preparations from both animals. Previous investigations clearly demonstrated that the haloperidol and spiperone binding of neuroleptic drugs correlated well with their pharmacological activities in the apomorphine test in rat<sup>6</sup> and dog<sup>20,22,23</sup> and their clinical potency<sup>17</sup>.

Fig. 2 Correlation between the  $IC_{50}$  values of  $^3H$ -spiperone binding in solubilised preparations from dog (●) and rat (○) and the antagonism of apomorphine-induced emesis in dog (see refs 22, 23).

Fig. 3 Distribution of stereospecific  $^3H$ -spiperone binding after centrifugation of a digitonin extract from dog striatum. 1 ml of soluble extract was layered on 12 ml sucrose gradient (15–30%) buffered with 10 mM sodium phosphate (pH 7.2) containing 0.03% digitonin and 0.01%  $Na_3$ . Centrifugation was run at 2–3 °C in SW 40 Ti rotor (Spinco) at 30,000 r.p.m. (111,700g,  $r_{av}$ ) for 16 h. Marker enzymes: catalase (CTL), lactate dehydrogenase (LDH) and malate dehydrogenase (MDH).

Stereospecific  $^3H$ -spiperone binding in soluble dog striatum preparations was found to be saturable ( $K_{D(app)}$  at 0 °C = 4.8 nM) and reversible ( $t_{1/2}$  dissociation at 5 °C = 49 min). A more detailed kinetic analysis will be presented elsewhere<sup>15</sup>. To assess the macromolecular nature of these binding sites, the soluble extract from dog striatum was submitted to sedimentation centrifugation through a sucrose gradient and then compared with the sedimentation of marker enzymes. The peak of binding sites seemed to migrate more rapidly than malate dehydrogenase (4.3S) and lactate dehydrogenase (7.0S), but more closely resembled that of catalase (11.3S). When compared with the sedimentation properties of muscarinic receptor<sup>14,15</sup>, the spiperone binding sites seemed to be more heterogeneous and to have a higher molecular weight (> 200,000).

The present results provide evidence that a macromolecular complex, able to bind  $^3H$ -spiperone stereospecifically, was solubilised from dog striatum. Most of the solubilisation criteria were fulfilled: not sedimentable at 262,000g ( $r_{av}$ ) for 60 min, absence of lamellar membrane structure in electron microscopy<sup>24</sup>, and low Svedberg coefficient compared with that of membranes.

Four lines of evidence indicate that the spiperone binding solubilised by digitonin from dog striatum and characterised by gel-filtration or sedimentation gradient is of dopaminergic nature. First, it was localised in the striatum but not in the cerebellum, and preliminary results showed that the binding sites solubilised from frontal cortex displayed a higher affinity for serotonin antagonists and a lower affinity for dopamine antagonists (in preparation). Second, in contrast to findings in the rat striatum, various dopamine antagonists from different chemical classes, chosen to display a wide range of activity, were nearly equiactive in the soluble and membrane preparation from dog striatum. Serotonin antagonists like pipamperone and mianserin were very poor inhibitors of  $^3H$ -spiperone binding to

soluble sites from striatum, whereas both drugs were very active in the frontal cortex<sup>6</sup>. Third, a tetraline derivative, known to be the most specific dopamine agonist<sup>6,25</sup>, and thus being inactive in the spiperone binding assay in the frontal cortex, inhibited the spiperone binding of the solubilised preparation of dog striatum at very low concentrations. Finally, the good correlation between the inhibitory effects of drugs in the soluble preparation and their antagonism of apomorphine-induced emesis is only possible if the relative high affinity of the dopamine receptors is maintained after the solubilisation process.

Thus, the above results provide evidence that the spiperone binding sites solubilised by digitonin treatment from dog striatum retain the characteristics of dopamine receptors.

We thank G. Aerts for technical assistance, J. Van Reempts and M. Borgers for electron microscopy examination, and D. Ashton for help in preparing the manuscript. Part of this work was supported by a grant from IWONL.

## Melanotropin potentiating factor is the C-terminal tetrapeptide of human $\beta$ -lipotropin

WE recently demonstrated that the molar pigmentary potency of human  $\beta$ -lipotropin ( $\beta$ -LPH) is greater than other melanocyte-stimulating hormones (MSHs) on *Anolis* skin; it is 2.6–4.0 times greater than  $\alpha$ -MSH<sup>1</sup> using the *Anolis* rate method of MSH bioassay<sup>2</sup>. We also found (unpublished) human  $\beta$ -LPH to be 2 to 4 times more potent than  $\alpha$ -MSH using the steady state (quantal<sup>3</sup>) method. This was due to a potentiation of the MSH sequence of  $\beta$ -LPH (LPH<sub>47–53</sub>) by a factor associated with  $\beta$ -endorphin (LPH<sub>61–91</sub>). We showed that the melanotropin potentiating factor (MPF) was not the opiate peptide, <sup>5</sup>Met-enkephalin (LPH<sub>61–65</sub>)<sup>4</sup>, and now report the identification of MPF as the sequence LPH<sub>88–91</sub>.

**Table 1** Intrinsic molar potencies of LPH peptide fragments calculated relative to  $\alpha$ -MSH

LPH Structure ( $\alpha$ -MSH)	Potency (1.000)
61–91	$5.036 \times 10^{-4}$ (4.813 and $5.270 \times 10^{-4}$ )
66–91	$3.590 \times 10^{-4}$ (3.406 and $3.785 \times 10^{-4}$ )
87–91	$1.409 \times 10^{-4}$ (1.377 and $1.442 \times 10^{-4}$ )
87(Bzl)–91	$1.667 \times 10^{-4}$ (1.574 and $1.765 \times 10^{-4}$ )
88–91	$3.245 \times 10^{-5}$ (3.067 and $3.434 \times 10^{-5}$ )
89–91	$4.427 \times 10^{-5}$ (4.101 and $4.780 \times 10^{-5}$ )
88–90	$4.266 \times 10^{-5}$ (4.027 and $4.520 \times 10^{-5}$ )
66–89	$2.967 \times 10^{-4}$ (2.797 and $3.148 \times 10^{-4}$ )
61–65, 70–89(D-Ala <sup>62</sup> , Leu <sup>65</sup> )	$2.548 \times 10^{-4}$ (2.432 and $2.670 \times 10^{-4}$ )
61–65, 76–89(D-Ala <sup>62</sup> , Leu <sup>65</sup> )	$2.105 \times 10^{-4}$ (1.992 and $2.225 \times 10^{-4}$ )
61–65, 81–89(D-Ala <sup>62</sup> , Leu <sup>65</sup> )	$8.588 \times 10^{-5}$ (8.269 and $8.920 \times 10^{-5}$ )
61–65, 85–89(D-Ala <sup>62</sup> , Leu <sup>65</sup> )	$7.586 \times 10^{-5}$ (7.205 and $8.199 \times 10^{-5}$ )
61–65, 88–89(D-Ala <sup>62</sup> , Leu <sup>65</sup> )	$5.237 \times 10^{-5}$ (4.921 and $5.573 \times 10^{-5}$ )
61–76	$2.245 \times 10^{-5}$ (2.095 and $2.406 \times 10^{-5}$ )
61–76 (D-Ala <sup>62</sup> , Leu <sup>65</sup> )	$8.878 \times 10^{-5}$ (8.375 and $9.412 \times 10^{-5}$ )
61–77	$2.245 \times 10^{-5}$ (2.095 and $2.406 \times 10^{-5}$ )
61–77 (D-Ala <sup>62</sup> , Leu <sup>65</sup> )	$6.140 \times 10^{-5}$ (5.884 and $6.408 \times 10^{-5}$ )
61–65	$6.890 \times 10^{-8}$ (6.764 and $7.017 \times 10^{-8}$ )

Dose-response curves were obtained to  $\alpha$ -MSH and the 18 peptide sequences, using the *Anolis* rate method of MSH bioassay<sup>2</sup>. Using analysis of variance<sup>8</sup>, the slope of the dose-response curves of the LPH peptide fragments did not differ significantly from that of  $\alpha$ -MSH ( $P > 0.05$ ). The 95% fiducial limits of the estimated potencies are given in parentheses.

The *Anolis* rate method of MSH bioassay<sup>2</sup> was used in these experiments. The peptides Tyr-Lys-Lys-Gly-Glu (human  $\beta$ -LPH<sub>87–91</sub>), its (tyrosyl) *O*-benzyl derivative [87(Bzl)-91], Lys-Lys-Gly-Glu (89–91), Lys-Gly-Glu (88–91), and Lys-Lys-Gly (88–90) were prepared by classical solution methods and characterised by TLC, paper electrophoresis and amino acid analysis of acid and/or enzymatic digests. Other peptides used in

**Fig. 1** The dose-related potentiation of  $\alpha$ -MSH potency by  $\beta$ -endorphin. Dose-response curves were obtained from eight two-fold dilution series of  $\alpha$ -MSH, seven of which had had added  $\beta$ -endorphin concentrations. The potencies of each  $\alpha$ -MSH dose-response curve in the presence of  $\beta$ -endorphin concentration was calculated relative to that in the absence of added  $\beta$ -endorphin. Thus each point on the graph represents the increase in  $\alpha$ -MSH potency with a  $\beta$ -endorphin concentration. The 95% fiducial limits of the estimated potencies are represented as vertical bars. There was a significant increase in  $\alpha$ -MSH potency with concentrations of  $16 \times 10^{-12}$  M  $\beta$ -endorphin or greater ( $P < 0.01$ ).

**Fig. 2** Potentiating activities of LPH fragments on  $\alpha$ -MSH potency. Bioassays of  $\alpha$ -MSH were performed with and without LPH peptide fragments in various concentrations. The dose-related potentiation of  $\alpha$ -MSH potency by each LPH fragment was measured as described in Fig. 1 and calculated relative to that of  $\beta$ -endorphin (LPH<sub>61-91</sub>) using a two-factorial assay system.

these experiments were prepared by N. N. Petter (ICI) by solid phase methods<sup>5</sup>.

Dose-response curves were obtained for  $\alpha$ -MSH and the synthetic LPH peptide fragments and their intrinsic molar potencies were calculated (Table 1). All showed negligible intrinsic MSH activity. Constant concentrations of the LPH peptide sequences were then incorporated into the twofold dilutions used to obtain the  $\alpha$ -MSH dose-response and their relative potencies were calculated.  $\beta$ -Endorphin potentiated  $\alpha$ -MSH potency with the dose-response curves remaining parallel. This potentiation was dose-related (Fig. 1) and the  $\alpha$ -MSH potency was increased to a maximum of 4.5-fold. To determine the sequence responsible for this potentiation, the potentiation activity of each peptide sequence was compared with that of  $\beta$ -endorphin (Fig. 2). Unequivocally, the results show that the sequence responsible for the potentiation is LPH<sub>88-91</sub>, Lys-Lys-Gly-Glu. Thus potentiating activity was abolished by the removal of the 88th or 91st amino acids from the tetrapeptide, while extension of the sequence to include tyrosine at position 87 did not increase potentiating activity further. The higher potentiating activity of LPH<sub>61-91</sub> ( $\beta$ -endorphin) and LPH<sub>66-91</sub> than LPH<sub>88-91</sub> was probably due to increased stability of the longer peptides as there was negligible activity in the sequences between LPH<sub>61</sub> and LPH<sub>89</sub>. These findings cannot be attributed to characteristics of the rate assay as we have obtained similar results (unpublished) with a steady state (quantal<sup>3</sup>) method. We therefore conclude that the melanotropic potentiating factor (MPF) is human LPH<sub>88-91</sub>, Lys-Lys-Gly-Glu. Whether MPF acts by stimulation of an independent receptor or by causing conformational changes is uncertain.

As a  $16 \times 10^{-12}$  M concentration of  $\beta$ -endorphin will potentiate MSH activity significantly (see legend to Fig. 1), the effect may be physiological. Although we have tested MPF activity on the *Anolis* skin, the unexpectedly high sebotropic<sup>6</sup> and neurotropic<sup>7</sup> potencies of  $\beta$ -LPH in the rat suggest that MPF may also modulate MSH peptide actions in the mammal and we are presently investigating this possibility.

## Inhibition of DNA synthesis *in vitro* by binding of benzo(a)pyrene metabolite diol-epoxide I to DNA

It has been shown that benzo(a)pyrene (BP) is a strong mutagen and carcinogen after metabolic activation by mixed function oxidases and epoxide hydratase. Evidence now indicates that ( $\pm$ )-7,8-dihydroxy-7,8,9,10-tetrahydrobenzo(a)pyrene (diol-epoxide I) is an ultimate carcinogenic and mutagenic form of BP<sup>1-4</sup>. This metabolic intermediate interacts covalently with nucleic acids<sup>5-8</sup>. Most binding to DNA, 80% of the total, occurs by coupling between the 2-amino group of guanine and the carbon 10 position of diol-epoxide I (ref. 5). Binding to adenine, less than 15% of the total, leads to partial denaturation of the DNA double helix<sup>6</sup>, and binding of diol-epoxide I to the phosphate groups of DNA results in DNA strand scission<sup>8</sup>. Intercalation of diol-epoxide I may cause conformational change of the DNA double helix<sup>6,7</sup>. Despite these extensive studies, the mechanism of alteration of the genetic function of DNA due to the binding of BP is not understood. We describe here a system which has enabled us to analyse the effect of BP binding to DNA on the replication of double-stranded circular DNA *in vitro*. pBR322 DNA (molecular weight,  $2.6 \times 10^6$ ) is an artificial plasmid DNA derived from ColE1 and pBR313 in *Escherichia coli*<sup>9</sup>. It carries the base sequence derived from ColE1 DNA at the site of origin of replication<sup>9</sup>. Like ColE1 DNA<sup>11-13</sup>, pBR322 DNA replicates semiconservatively and completely in a crude lysate of *E. coli*.

The binding of diol-epoxide I to pBR322 DNA was performed as described previously<sup>6</sup>. The number of diol-epoxide I molecules covalently bound to DNA, the molar ratio (MR), was determined using the radioactivity of <sup>14</sup>C-di-epoxide I (29.4 mCi mmol<sup>-1</sup>, NCI), UV absorption (254 nm), fluorescence and the molecular weight of pBR322 DNA. The covalent binding increased linearly as a function of increasing dose of diol-epoxide I concentration in the reaction mixture. High pressure liquid chromatography (Waters Bondapak C18

**Fig. 1** Assay of the incorporation of  $^{32}\text{P}$ -TMP into pBR322 DNA<sup>11,13</sup>. *E. coli* YS1 cells were grown in 600 ml OC medium enriched by 0.4% Bacto-Peptone (Difco) and 0.1% yeast extract (Difco). When the number of cells reached  $2 \times 10^8$  per ml, chloramphenicol was added ( $180 \mu\text{g ml}^{-1}$ ). The culture was then incubated for 2 h. The cells were washed with 50 mM potassium phosphate buffer (pH 7.4), suspended in 0.6 ml of 15% sucrose–75 mM potassium phosphate buffer (pH 7.4) and frozen in a dry ice–isopropanol bath. The crude cell extract was prepared by thawing cells in an ice–water bath, and the volume adjusted to 1.5 ml with 10% sucrose–50 mM phosphate buffer (pH 7.4). To the cell suspension 60  $\mu\text{l}$  2 M KCl, 150  $\mu\text{l}$  lysozyme ( $4 \text{ mg ml}^{-1}$ ) and 40  $\mu\text{l}$  5% Brij 58 were added at  $0^\circ\text{C}$  and mixed with a vortex mixer. After 30 min at  $0^\circ\text{C}$ , the mixture was centrifuged at 30,000 r.p.m. for 30 min in a Beckman SW 50.1 rotor. The standard assay mixtures (200  $\mu\text{l}$ ) were 25 mM potassium phosphate buffer, 67 mM KCl, 7.5 mM  $\text{MgCl}_2$ , 0.2 mM each of rNTPs, 25  $\mu\text{M}$  each of dNTPs, 2 mM spermidine, and contained 2  $\mu\text{g}$  pBR322 DNA,  $^{32}\text{P}$ -TTP (0.2  $\mu\text{Ci}$ ) and 40% cell extract. The assay was performed at  $30^\circ\text{C}$ . 30  $\mu\text{l}$  aliquots were taken at the times shown, precipitated with 10% trichloroacetic acid–0.1 M pyrophosphate, collected on filters (Whatman GF/C, 25 mm) and washed with 0.1 M HCl followed by ethanol. The open symbols indicate the standard assay mixture. Closed symbols indicate that rifampicin was added to the assay mixture. Control pBR322 DNA (MR = 0,  $\circ$ ,  $\bullet$ ); pBR322 DNA-bound diol-epoxide I (MR = 1.4,  $\triangle$ ,  $\blacktriangle$ ); pBR322 DNA-bound diol-epoxide I (MR = 5.8,  $\square$ ,  $\blacksquare$ ).

column,  $\text{H}_2\text{O}$  to 100% methanol gradient) of late elutant ( $\sim 570 \text{ ml}$ ) from Sephadex LH-20 column chromatography of enzymatically hydrolysed DNA supported our calculation of the MR (data not shown).

Incubation of unmodified pBR322 DNA (control) in an extract from *E. coli* cells resulted in the incorporation of  $^{32}\text{P}$ -TMP into the acid-precipitable fraction (Fig. 1). The incorporation increased linearly for at least 90 min. This incorporation was inhibited completely by the addition of rifampicin ( $25 \mu\text{g ml}^{-1}$ ) at zero time. Rifampicin inhibits RNA-primed initiation of DNA synthesis but does not affect the elongation of the deoxypolynucleotide chain<sup>11</sup>. When DNA covalently bound to diol-epoxide I (MR = 1.4) was used, the incorporation of  $^{32}\text{P}$ -TMP was reduced about 30% (Fig. 1). From MR = 0 to MR = 5.9 the rate of reduction was linear with the number of diol-epoxide I molecules bound to one pBR322 DNA molecule.

When MR = 5.9 the initial incorporation (up to 20 min) was normal, but the total  $^{32}\text{P}$ -TMP incorporation after 100 min was almost completely inhibited.

To study the mechanisms whereby DNA synthesis is inhibited by the binding of diol-epoxide I, we analysed the newly synthesised daughter strand DNA by sucrose density gradient centrifugation. The closed circular DNA synthesised *in vitro* appeared as a single peak with a skewed portion towards higher molecular weight in a neutral sucrose density gradient. Evidently the skewed portion represents closed circular DNA associated with newly synthesised DNA fragments. The amount of the closed circular DNA synthesised from DNA bound to diol-epoxide I (MR = 1.4) was about 30% less than that of the control (data not shown).

**Fig. 2** Analysis of newly synthesised DNA products in alkaline sucrose density gradient. Assays were performed as described in the legend to Fig. 1. Samples were taken at 30 min (a–c) and 60 min (d–f). The reaction was stopped by the addition of one-fifth volume of 0.1 M EDTA (pH 8.0)–1% SDS. After addition of one-fifteenth of the original volume of 1.5 M NaCl–0.15 M sodium citrate, samples were treated twice with a chloroform–isoamylalcohol mixture (24:1, v/v). After the centrifugation (5,000 r.p.m., 30 min at  $4^\circ\text{C}$ ), the aqueous phase was dialysed against 50 mM Tris–HCl (pH 8.0)–50 mM EDTA–0.5 M NaCl. A 0.1 ml aliquot of each dialysed sample was treated with 0.24 M NaOH and applied to an alkaline sucrose density gradient (5–20%)<sup>16</sup>. a, d, Control, MR = 0; b, e, MR of diol-epoxide I is 1.4; c, f, MR of diol-epoxide I is 5.8.

Figure 2 shows the alkaline sucrose density gradient profile of the product DNA. In normal conditions (MR = 0), the newly synthesised closed circular DNA banded near the bottom of the gradient (fractions 6–8). Unit sized single linear and single circular molecules banded at fractions 30 (15S). A peak which appeared at the top of the gradient (fractions 42–47) represents the 6S initiation fragments dissociated from the origin of pBR322 DNA replication<sup>11,13</sup>. The size classes of DNA synthesised during the first 30 min of incubation are identical and unrelated to the number of diol-epoxide I molecules bound to template DNA as observed. The only exception is that more 6S fragments accumulated in unmodified pBR322 DNA than in modified DNA, indicating that the formation of initial 6S fragments was slightly inhibited by diol-epoxide I binding.

After 60 min of incubation, about four times more closed circular molecules had been synthesised from unmodified DNA than after 30 min (Fig. 2a, d). When diol-epoxide I was bound to DNA at MR = 1.4, the closed circular DNA synthesised was only doubled after an additional 30 min incubation (Fig. 2b, e). When MR = 5.8, the amount of closed circular DNA did not increase after an additional 30 min incubation (Fig. 2c, f). The number of unit-sized single-stranded linear or circular molecules (15S) markedly increased when intact DNA was subjected to replication as shown in Fig. 2a, d. This class of DNA also increased as much as that in the control experiment from 30–60 min when the DNA was bound to 1.4 molecules of diol-epoxide I (Fig. 2b, e). However, the peak at fractions 26–32 (15S) in Fig. 2e is markedly skewed towards the top of the gradient. Moreover, when the molar ratio was 5.8, there was no distinctive peak observed in the region of fractions 26–33 (Fig. 2f). In contrast to other classes of DNA, the relative proportion of 6S molecules synthesised did not change significantly in either control or modified DNA during an additional 30 min incubation. These results indicate that many intermediate sized newly synthesised DNA fragments with length less than the unit size of pBR322 DNA were accumulated when diol-epoxide I modified DNA was subjected to replication. The effect of covalently-bound diol-epoxide I is therefore to inhibit chain elongation with little effect on the initiation of DNA replication.

Note that pBR322 DNA, which carries the same base sequence as ColE1 DNA at the initiation site, consists of a high proportion of adenine and thymine residues<sup>10</sup>, which have significantly less chemical reactivity with diol-epoxide I than guanine residues<sup>5–7</sup>. Based on these findings and other studies, it may be reasonable to assume that the initiation site of DNA replication is free from the binding of diol-epoxide I and is therefore capable of generating a normal initiation of DNA synthesis when the molar ratio is small. The elongation of the deoxypolynucleotide chain was effectively blocked at the binding site of the template molecule. Hsu *et al.* have reported similar results regarding the inhibition of converting single-stranded  $\Phi$ X174 DNA to double-stranded circular DNA<sup>14</sup>.

Another question is whether the binding of diol-epoxide I completely blocks the elongation of the nascent DNA chain or whether the binding site can be excised and repaired, allowing

**Fig. 3** Analysis of heat-treated ColE1 DNA modified with diol-epoxide I in an alkaline sucrose density gradient centrifugation. Tritium-labelled ColE1 DNA was prepared after amplification with chloramphenicol as described previously<sup>16</sup>. The purified ColE1 DNA was modified with diol-epoxide I as described in the text. Unmodified ColE1 DNA (a) and modified ColE1 DNA (MR = 1.4) (b) were treated at 90 °C for 5 min in 5 mM Tris-HCl (pH 8.0)–5 mM EDTA–50 mM NaCl, and then the pH was adjusted to pH 12 with 4 M NaOH. Samples were analysed by the 5–20% alkaline sucrose density gradient as shown in the legend to Fig. 2.

**Fig. 4** Newly synthesised pBR322 DNA with (a) and without (b) diol-epoxide I (MR = 0 and 1.4 respectively) was analysed in an alkaline sucrose density gradient before and after heat-treatment. pBR322 DNA was subjected to the *in vitro* assay system for 60 min as described in the legend to Fig. 1. The product was analysed in the alkaline sucrose density gradient centrifugation with (dashed line) and without (solid line) heat-treatment as shown in the legend to Fig. 3.

the completion of replication. To investigate this, a method was devised to detect a small number of binding sites on closed circular DNA. About 50% of the closed circular DNA (MR = 0) was converted to single-stranded circular and linear forms in an alkaline sucrose density gradient after heat treatment of the DNA at 90 °C for 5 min (Fig. 3a). The conversion of 50% is a result of alkaline hydrolysis of the RNA segment which is presented in chloramphenicol-amplified ColE1 DNA<sup>15</sup>. The rate of conversion was clearly increased when diol-epoxide I was bound to ColE1 DNA (MR = 1.4), heated and analysed in an alkaline sucrose density gradient (Fig. 3b), indicating that the binding site itself is heat-alkali-labile. This provides a sensitive assay method for the detection of bound diol-epoxide I on DNA strands. When the method was applied to the DNA which had completed a round of replication (for method see legend to Fig. 2), the rate of conversion from closed circular to the other forms was no different for the control and modified (MR = 1.4) DNA (Fig. 4).

These results suggest that the parent strands no longer possess diol-epoxide binding sites which were present before replication and also rule out the possibility of the binding sites in the template being bypassed during replication. Excision of diol-epoxide-damaged DNA from the parental strand would best explain the reduction in the rate of DNA elongation described earlier.

We thank Drs H. V. Gelboin, J. Tomizawa and Y. Sakakibara for their advice and B. Welp for technical assistance.

## Suppression of a yeast *amber* mutation in *Escherichia coli*

THE complementation of *Escherichia coli* auxotrophs by cloned eukaryotic genes<sup>1-4</sup> makes it possible to use standard bacterial genetic techniques to study these eukaryotic genes. Here, we describe the cloning of a *Saccharomyces cerevisiae* (yeast) gene with an *amber* suppressible allele. Reversion and suppression properties of this allele are examined in growing *E. coli* cells.

The yeast *his3* gene coding for imidazoleglycerolphosphate (IGP) dehydratase was cloned as a hybrid of bacteriophage  $\lambda$  which complemented *hisB* auxotrophs of *E. coli* lacking the analogous activity<sup>1</sup>. The wild type yeast *his3* gene is transcribed and translated in *E. coli* with high fidelity to produce an enzyme activity strongly resembling the activity found in yeast cells<sup>2</sup>. Complementation analysis of many derivatives containing *his3* sequences indicates that the *his3* structural gene is localised to a region of approximately 700 base pairs<sup>3</sup>. The length and location of this *E. coli* complementation unit is similar to the region homologous to the 650 base poly(A)-containing RNA species found in yeast cells (K. S., unpublished).

Genetic analysis in *E. coli* of the yeast *his3* gene depends on the availability of cloned derivatives which are nonfunctional. Mutant *his3* genes which are nonfunctional in *his3*<sup>-</sup> yeast cells are also nonfunctional when cloned and propagated in *E. coli*; that is, they do not complement *E. coli hisB* auxotrophs<sup>2</sup>. The order of two such *his3* lesions has been established by a three-factor cross of the bacteriophage  $\lambda$  hybrids containing the cloned mutant genes<sup>2</sup>. Non-complementing deletions of the yeast *his3* gene spontaneously generated during lytic growth of a bacteriophage  $\lambda his3$  hybrid have been isolated<sup>5</sup> by the method of Parkinson and Huskey<sup>6</sup>. The physical locations of the yeast lesions have been determined by deletion mapping in *E. coli*<sup>5</sup>. Deletion mutants which require transcriptional initiation from the  $\lambda$  promoter P<sub>L</sub> for *his3* expression have been used to define a yeast DNA sequence which functions in *E. coli* as a promoter<sup>7</sup>. Derivatives of a  $\lambda his3$  hybrid which overproduces IGP dehydratase activity in *E. coli* have also been isolated (M. Brennan and K. S., unpublished results).

The demonstration that cloned yeast genes can be reintroduced into yeast cells by transformation and expressed<sup>8</sup>

makes it possible to fuse the genetic systems of *E. coli* and *S. cerevisiae*. Recent findings indicate that DNA transformation of yeast can occur by at least three mechanisms (ref. 9 and J. B. Hick, A. Hinnen and G. R. F., unpublished results). Depending on the particular mechanism, transforming DNA can integrate into the yeast chromosomes by homologous recombination and/or replicate autonomously. Introduction of physically and genetically defined cloned *his3* derivatives into yeast cells should be an important tool in elucidating mechanisms of yeast regulation, DNA replication and recombination.

To aid such studies it would be useful to clone a conditionally lethal yeast mutation. Strain constructions would be significantly facilitated and interpretation of experimental results would be strengthened by the conditional nature of the lesion. To isolate a conditionally lethal lesion, 112 independently derived *his3* mutants of yeast<sup>10</sup> were screened for *amber* suppressibility by scoring for histidine prototrophy following mating with *his3*-532 SUP4-2. Three mutants (*his3*-14, *his3*-19 and *his3*-X5-21B) presumably containing internal UAG codons suppressible by tyrosine-inserting tRNAs<sup>11</sup> were isolated. DNA from strain *his3*-X5-21B was cloned in  $\lambda$ gt4 (ref. 12) by the *EcoRI*-DNA ligase method<sup>2</sup>. From this pool of  $\lambda$ gt4 hybrids, a phage containing *his3* sequences was isolated by the plaque filter hybridisation method of Benton and Davis<sup>13</sup>. The 10.1 kb (kilobase pair) *EcoRI* fragment in this phage, Sc2693, is physically indistinguishable from the analogous fragment (Sc2601) which complements *E. coli hisB* mutations.  $\lambda$ gt4-Sc2693 does not complement *hisB*463; therefore, the phage contains a cloned yeast *his3* gene with an *amber* lesion. The *his3* gene is located internally within a 1.7 kb *Bam*HI fragment of Sc2601 DNA<sup>5</sup>. The equivalent *Bam*HI DNA fragments of  $\lambda$  hybrids containing *his3* mutant genes were cloned in the yeast vectors YIp5 and YRp7 (ref. 9). The sources of these cloned mutant genes were  $\lambda$ gt1-Sc2612 (*his3*-38),  $\lambda$ gt6-Sc2679 (*his3*-532) (ref. 2), and  $\lambda$ gt4-Sc2693 (*his3*-X5-21B).

All mutant *his3* genes cloned in these yeast vectors were introduced into the *E. coli* strain *hisB*463 by selection for the plasmid-coded gene for ampicillin resistance. The spontaneous reversion rates in *E. coli* of these yeast lesions were measured and compared to the spontaneous reversion rates in yeast (Table 1). The comparison is complicated by the fact that in these *E. coli* cells, the *his3* genes are presumably present in about 20 copies, and that the expression is only about four times above the single copy level<sup>7</sup>. The reversion rates are measured as His<sup>+</sup> colonies obtained per cell. It is unclear how these numbers are related to number of reversion events per DNA molecule. Multiple copies of *his3*-38 in *hisB*463 cells allow some growth in the absence of histidine. The reversion rate of this lesion in *E. coli* as determined from plasmid hybrids ( $2 \times 10^{-8}$ ) agrees well with the previous results obtained with phage hybrids<sup>2</sup>. The reversion rate of this lesion in yeast is significantly lower ( $<10^{-9}$ ). *his3*-532 is a very stable lesion in both organisms, though revertants are detected in *E. coli* but not in yeast *his3*-X5-21B reverts in *E. coli* at a significantly lower rate than it reverts in yeast. These results indicate that spontaneous reversion of a given yeast lesion occurs at different rates in yeast and in *E. coli*.

Table 1 Suppression and reversion characteristics of yeast *his3* lesions

<i>his3</i> lesion	$\lambda$ Hybrid	Plasmid hybrid	<i>hisB</i> (supF)	<i>his</i> <sup>+</sup> colonies <i>hisB</i>	Yeast
<i>his3</i> -38	$\lambda$ gt1-Sc2612	YIp5-Sc2719	$2 \times 10^{-8}$	$3 \times 10^{-8}$	$<10^{-9}$
		YRp7-Sc2719	$1 \times 10^{-8}$	$1 \times 10^{-8}$	
<i>his3</i> -532	$\lambda$ gt6-Sc2679	YIp5-Sc2720	$2 \times 10^{-10}$	$1 \times 10^{-10}$	$<10^{-10}$
		YIp5-Sc2721	1	$3 \times 10^{-9}$	
<i>his3</i> -X5-21B	$\lambda$ gt4-Sc2693	YRp7-Sc2721	1	$1 \times 10^{-9}$	$2 \times 10^{-7}$

As *his3*-X5-21B is suppressed in yeast by a tyrosine-inserting tRNA, suppression in *E. coli* was examined with an analogous tRNA species (*supF*). *hisB463* cells containing the cloned yeast *his3* lesions were lysogenised by a phage ( $\phi 80$  *supF*) containing the *E. coli* gene coding for a tRNA species capable of suppressing amber (UAG) codons<sup>14</sup>. Introduction of the *supF* allele into these *hisB463* derivatives was determined by their ability to plate  $\lambda$ cI857Sam7. *hisB463* cells containing both the *his3*-X5-21B and the *supF* alleles grow in the absence of histidine (Table 1); that is, the *his3* lesion is suppressed by *supF*. This result is not due to an artefact of selection, as both the *his3*-X5-21B and the *supF* alleles were introduced into the *hisB463* host by non-selective means. Furthermore, it confirms the amber suppressibility of the *his3*-X5-21B allele. It is now possible to introduce DNA containing this conditionally lethal yeast gene back into yeast and *E. coli*.

These results indicate that an *E. coli* amber-suppressing tRNA species suppresses a yeast amber lesion in growing *E. coli* cells. It has been previously established that purified yeast suppressor tRNAs, when present in heterologous, eukaryotic, *in vitro* translation systems, suppress prokaryotic (Q $\beta$ ) amber mutations<sup>15,16</sup>. Taken together, these *in vivo* and *in vitro* experiments provide evidence that translational termination and tRNA suppression of nonsense codons are processes which are conserved between prokaryotic and eukaryotic organisms.

## Genotype control of the dystrophin muscularis gene in mice

MUTANTS of the dystrophin muscularis gene (*dy*) in mouse suffer from progressive skeletal muscle loss, together with inadequate repair or regeneration<sup>6</sup>. In 1974 I reported a distinctive phenotypic difference between two dystrophic mutant alleles with respect to myogenesis *in vitro*<sup>1</sup>. Homozygous *dy*<sup>21</sup> mice gave cultures in which there was apparently normal myogenesis, whereas mice homozygous for *dy* gave cultures which contained large numbers of grouped uninucleate myoblasts

Fig. 1 Unstained living cultures photographed with phase contrast-optics. The structures are typical and the illustrations representative of the experimental results. a, C57 +/+, normal multinucleate myotube; b, C57 *dy*<sup>21</sup>/*dy*<sup>21</sup>, large syncytial myotube; c, C57 *dy*/*dy*, a definite multinucleate myotube; d, 129 *dy*/*dy*, characteristic pseudostraps with discrete uninucleate cells. All photographs were taken at 4 d *in vitro* in identical conditions.

(pseudostraps) in place of multinucleate syncytial myotubes<sup>2</sup>. MacPike, however, showed<sup>3</sup> that muscular dystrophies caused by these two alleles carried in the same genetic background (C57BL/6J) were similar when assessed histologically. I have, therefore, investigated how the process of myogenesis *in vitro* (which can be considered to be another independent function of the muscle) is affected not only by the two allelic mutants but also by the genetic background. The *dy* dystrophy was known to be histologically similar in either the C57BL/6J or 129/ReJ background<sup>3</sup> but surprisingly C57BL/6J *dy*/*dy* cultures gave normal myogenesis while 129/ReJ *dy*/*dy* cultures again produced pseudostraps.

The mice used in this series of experiments were C57BL/6J *dy*<sup>21</sup>/*dy*<sup>21</sup>, C57BL/6J *dy*/*dy*, C57BL/6J +/+ and 129/ReJ *dy*/*dy* at 2, 3, 4 and 5 months of age. Cultures were obtained from 4 day crush lesions as described previously<sup>1</sup>. Daily examination for a period of 8 days was carried out blind; 48 cultures of each genotype were assessed. As before, the pattern of growth during the first 3 days was one of proliferation and explant spreading. Myotubes, increasing in size and number, developed by days 4 to 8 in all three C57BL/6J genotypes including the *dy* mutant (Fig. 1a, b, c). The 129/ReJ *dy*/*dy* showed without exception the characteristic pseudostraps (Fig. 1d) and the occasional small myotube during the first 3 days.

*In vitro* the 129/ReJ *dy* muscle attempts to form myotubes but does not succeed<sup>1</sup>. However, the same muscle in a more complex organotypic culture of fetal spinal cord and muscle exhibits some regeneration<sup>4</sup> although it is much less than normal muscle in the same conditions. Furthermore, the *dy* muscle cells cultured as a low density monolayer<sup>5</sup> produce apparently normal myogenic colonies which contain well differentiated muscle fibres. Clearly, myogenesis from dystrophic muscle is extremely susceptible to environmental conditions. But it is also

clear from the experiments reported here that there is a positive indication of a genotypic control over dystrophic myogenesis.

The consequence of these findings of the interaction between the gene at the *dy* locus and any other genes of a particular background is clearly important with regard to the interpretation of experiments, past and future.

I thank Professor F. L. Mastaglia and Dr A. Montgomery for discussions. This work was supported by the Muscular Dystrophy Group of Great Britain.

## Sensitivity of low molecular weight RNA synthesis to UV radiation

RNA SPECIES C and D (nomenclature of Weinberg and Penman<sup>1</sup>) are among the most abundant of the long-lived<sup>2</sup>, homodisperse, low molecular weight nuclear RNAs<sup>3</sup>, and are present in all vertebrates tested<sup>4</sup>, but their function is unknown. They have several interesting characteristics: they seem to be transcribed from multiple-copy genes ( $10^2$ - $10^3$  genes per genome)<sup>5,6</sup>, to pass through the cytoplasm for a few minutes shortly after their transcription<sup>3,7-10</sup>, to have 5'-end caps that are very similar to those of eukaryotic mRNAs<sup>11,12</sup>, and to be present in heterogeneous nuclear RNA-protein particles<sup>13,14</sup>. Here, we show that C and D RNA syntheses are unexpectedly sensitive to UV radiation in HeLa cells. The effect of UV radiation on RNA synthesis has been used to study the organisation of transcription units<sup>15</sup>. UV irradiation, causing random formation of pyrimidine dimers in DNA, results in premature termination of transcription. The probability of causing a UV lesion within a transcription unit is directly proportional to its length, making it possible to measure the distance between a gene and its promoter. The present UV sensitivity data are compatible with the transcription units for the low molecular weight (less than 200-nucleotide long<sup>1,11,12</sup>) RNA species C and D being as long as 5 kilobases.

In this study, RNA was extracted from whole cells and analysed by polyacrylamide gel electrophoresis. Figure 1 shows an example of the routine assay used. Recovery variations were corrected by the <sup>14</sup>C-labelled RNA bands, as the cells had been incubated with <sup>14</sup>C-uridine for 1 d before the experiment. The briefly labelled RNA migrating between 5S and 4S RNA seems to be mainly 4S RNA precursors<sup>16,17</sup>, and so it was included in the estimations of newly made 4S RNA. If any RNA fragments were generated by UV effects on large transcription units<sup>18</sup>, they might have raised the radioactivity background in the gel electrophoresis pattern. This would not have affected our estimates, because only the counts of a given peak above this background were computed. These results would not have been affected by any possible effect of UV radiation on the cytoplasmic-nuclear maturation of C and D RNA, as whole cell RNA was assayed.

Figure 2a shows the sensitivity of the synthesis of 45S rRNA to UV radiation. It is assumed that brief labelling of RNA (20 min with <sup>3</sup>H-uridine) approximates RNA synthesis, as precursor pools do not seem to be affected by UV radiation<sup>18</sup>. The UV dose that resulted in a 37% level of residual synthesis ( $D_{37}$ ) was near 8 s when the incident dose rate was  $34 \text{ erg mm}^{-2} \text{ s}^{-1}$ .

The resulting product is almost identical to the  $D_{37}$  incident dose of  $270 \text{ erg mm}^{-2}$  reported for mouse L cell 45S rRNA synthesis<sup>19</sup>. Figure 2b and c shows that the synthesis of C and D RNA was inhibited, whereas the synthesis of 4S and 5S RNA was essentially unaffected at this dose range of UV radiation, as had been shown by Goldberg *et al.*<sup>20</sup>. In addition, the inactivation curve for both C and D RNA synthesis deviated from exponential kinetics (Fig. 2b, c). The  $D_{37}$  value for both C and D RNA synthesis, calculated by first order approximation of the initial slope (broken straight lines in Fig. 2b, c), was nearly 30 s. At an incident dose rate of  $34 \text{ erg mm}^{-2} \text{ s}^{-1}$ , the  $D_{37}$  incident dose for C and D RNA synthesis is then about  $1 \times 10^3 \text{ erg mm}^{-2}$ . The  $D_{37}$  incident dose for 18S rRNA synthesis is  $880 \text{ erg mm}^{-2}$  (ref. 19), whereas the distal end of the 18S rRNA gene is located about 5 kilobases from its promoter, as determined by electron microscopic<sup>21</sup> and UV transcription mapping<sup>19</sup>.

Two models could account for our results. Based on the  $D_{37}$  value, the C (or D) RNA sequences would be derived from 4-5-kilobase-long transcription units, and according to the deviation from exponential kinetics, several C (or D) RNA genes would be tandemly arranged behind a common promoter<sup>19</sup>. It can then be estimated that at least seven gene copies would exist per transcription unit<sup>19</sup>. Alternatively, the present data are compatible with the synthesis of a population of original transcripts which are heterogeneous in size, vary in length between approximately 0.5 and 5 kilobases, and which have a C (or D) RNA sequence at or near the 3'-terminus of each polynucleotide. Either model is unexpected because the known precursors to C and D RNA are about 0.2 kilobases long<sup>9,22</sup>. The precursors of C and D RNA, which are only slightly larger than the mature species, can be detected after at least 4 min of labelling<sup>7</sup>. It therefore follows that the proposed large original transcripts would be cleaved shortly after or during transcription.

There is no detectable repair of the lesions responsible for premature termination of transcription of rRNA<sup>19</sup>, histone<sup>23</sup> and adenovirus type 2 (ref. 24) genes, for at least 60-90 min after UV irradiation of mammalian cells. Therefore, it seems unlikely that repair of UV damage would significantly affect our results in the 30 min after UV irradiation in the present experiments. In any case, the unusual feature of the present data is the high sensitivity to UV radiation of C and D RNA synthesis, and fast repair would have only masked some of this sensitivity. It could be argued that the proposed interpretations of the data might be erroneous because UV radiation may affect transcription by various eukaryotic RNA polymerases differently. It has already been shown that UV transcription mapping works well with transcription by RNA polymerases class I and II (refs 19, 20, 25, 26), and one of these two types of polymerase is suspected to be involved in the synthesis of C and D RNA<sup>27,28</sup>. It

**Fig. 1** Polyacrylamide gel electrophoresis patterns of large (a) and small (b) RNAs from whole cells. HeLa S3 cells were labelled for 1 d with <sup>14</sup>C-uridine<sup>7</sup>, and then exposed to UV irradiation<sup>2</sup>, placed at 15 cm from a GE G2578 lamp (incident dose rate of  $34 \text{ erg mm}^{-2} \text{ s}^{-1}$ ). The cells were then spun down, and resuspended at  $2 \times 10^6$  cells  $\text{ml}^{-1}$  in medium and serum; after 10 min at  $37^\circ \text{C}$ , [<sup>3</sup>H-5]uridine ( $20 \mu\text{Ci ml}^{-1}$ ,  $26 \text{ Ci mmol}^{-1}$ ) was added, and the cells were finally collected after labelling for 20 min at  $37^\circ \text{C}$ . RNA was extracted from whole cells with phenol and SDS at  $55^\circ \text{C}$ , and analysed by 2.4% (a) and 10% (b) polyacrylamide gel electrophoresis as described elsewhere<sup>29</sup>. ■, <sup>3</sup>H (contracted scale); ●, <sup>3</sup>H (expanded scale); ○, <sup>14</sup>C.

**Fig. 2** Effect of UV radiation on labelling of several RNAs in HeLa cells. *a*, 4S rRNA; *b*, C RNA (●), 4S RNA (□) and 5S RNA (○); *c*, D RNA. The broken lines represent pseudo-first-order approximations to the experimental data. All conditions were as indicated in the legend to Fig. 1.

seems unlikely that C and D RNA could be synthesised by RNA polymerase class III, because in the presence of  $\alpha$ -amanitin, when 5S and 4S RNA synthesis is essentially unaffected, the synthesis of C and D RNA is markedly inhibited<sup>28</sup>.

I thank Dr W. Sauerbier for valuable suggestions during the preparation of the manuscript, and C. M. Reisch, S. I. Hsu and B. L. Careklas for assistance. This work was supported by NIH grants GM-22463 and CA-20683.

## ***Azotobacter* cytochrome *b*<sub>557.5</sub> is a bacterioferritin**

FERRITIN is the presumed iron storage protein of mammalian<sup>1</sup>, plant<sup>2</sup> and certain fungal<sup>3</sup> systems. The nitrogen-fixing bacterium *Azotobacter vinelandii*, produces a *b*-type cytochrome containing large amounts of non-haem iron and no labile sulphide, as first shown by Bulen *et al.*<sup>4</sup>. Here we present

evidence which reveals this protein to be a ferritin-like species, thus constituting the first authenticated occurrence of ferritin in a bacterium. The interesting redox properties of this molecule, bacterioferritin-cytochrome, are presented and discussed.

The cytochrome *b*<sub>557.5</sub> was prepared by the method of Bulen *et al.*<sup>4</sup> from N<sub>2</sub>-fixing *A. vinelandii* cells collected after they had entered the stationary phase. The purification method for this acidic protein involves heat treatment, protamine sulphate precipitation, dissolution by cellulose phosphate treatment and repeated crystallisation by the addition of Mg<sup>2+</sup>. The preparation is homogeneous on polyacrylamide gel electrophoresis, and SDS gel electrophoresis reveals a single subunit. The Fe content of 2.8–3.5  $\mu$ mol Fe per mg protein requires about 100 iron atoms per haem molecule in the preparation. As the iron constitutes 13–20% of the weight of the protein, we investigated the possible relationship of this protein to ferritin.

**Fig. 1** *a*, Small portion of a transmission electron micrograph of a crystalline sample of bacterioferritin-cytochrome of *A. vinelandii*. Sample preparation involved fixation with glutaraldehyde, dehydration with ethanol and embedment in Spurr's low viscosity embedding medium. No stain was used. *b*, Schematic idealisation of the dense inner region and 'transparent' outer shell of the bacterioferritin-cytochrome as revealed in the electron microscope. The regions are assigned, respectively, to the Fe core and protein shell.

Table 1 compares various analytical properties of this molecule with those of horse spleen ferritin<sup>5–8</sup>. SDS gel electrophoresis reveals a single subunit of molecular weight (MW) 17,000, slightly smaller than that of mammalian ferritin<sup>6</sup>. Amino acid analysis shows the expected dominance of acidic amino acids and yields a nearest integer MW of 17,185. Although the similarity to ferritin is already apparent, the most striking indication of the ferritin nature of the protein comes from electron microscopy of the unstained crystalline preparation. The portion of an electron micrograph shown in Fig. 1 reveals the presence of electron-dense cores of  $\sim 55$  Å diameter within approximately spherical electron transmitting shells of diameter  $\sim 105$  Å. The outer shells are presumed to be of protein, and the inner core must contain an iron compound (see below). These dimensions are virtually identical to those found by electron microscopy for mammalian ferritin<sup>9</sup>. Similarly, the apparent variable occupancy of the inner cores parallels that found in ferritin<sup>1–3,9</sup>.

Crystalline samples of the molecule have been studied by Mössbauer spectroscopy of <sup>57</sup>Fe at natural abundance by Lang and Spartalian (in preparation), and reveal a quadrupole-split doublet characteristic of Fe<sup>3+</sup> at 77 K. As the temperature is lowered to 1.5 K, a six-line magnetically split multiplet appears. The limiting high and low temperature spectra are virtually identical to those found previously<sup>10–12</sup> for horse ferritin. Magnetic susceptibility of the *Azotobacter* protein at 34 °C by the Evans NMR method<sup>13</sup> gives a magnetic moment,  $\mu_{\text{eff}} = 3.7$  Bohr magnetons per Fe atom. The same experiment for horse spleen ferritin (Sigma) also yields 3.7 BM per Fe atom, in

agreement with previous work<sup>14,15</sup>. The Mössbauer and susceptibility experiments together establish the weakly coupled high-spin ferric nature of the bulk iron.

The combined information from the mode of preparation and crystallisation, the high Fe content, the electron microscopy, the amino acid composition, the subunit MW, the Mössbauer spectra and magnetic susceptibility, lead us to conclude that this protein represents the first example of a bacterioferritin.

It was the presence of haem that led to the original purification of the protein<sup>4</sup>. The electronic spectrum of the oxidised form has a Soret band at 417 nm as the only distinct peak in the visible region<sup>4</sup>. On reduction with  $S_2O_4^{2-}$ /methyl viologen, we find a clean reduced cytochrome spectrum with  $\alpha$ ,  $\beta$  and Soret bands at 557.5, 527 and 425 nm, respectively.

To show the intimate association of haem with this bacterioferritin, we note first that extensive dialysis and repeated recrystallisation can be accomplished without change in composition. Further, polyacrylamide gel electrophoresis, isoelectric focusing and gel-filtration chromatography each reveal a homogeneous preparation and establish the inseparability of haem and non-haem iron components of the protein. Although the haem has been identified as protoporphyrin IX (ref. 4), quantitative determination by the pyridine haemochromogen method is precluded by variable absorption (or occlusion) of haem by the precipitated non-haem iron cores. Haem was therefore determined by treatment with formic acid, which unfolds the protein, solubilises the non-haem iron and presumably stabilises the ferrihaem as the formic acid complex. With protein determined by the Lowry procedure<sup>16</sup> and haem absorption in formic acid standardised with haemin chloride or haemoglobin, we initially find an average of 37,000 daltons per haem. We note that one haem for two subunits requires 34,000 daltons per haem. In addition to the apparent inseparability of the haem and non-haem iron and the roughly constant haem/protein ratio, the redox properties of the protein show an intimate relationship of haem and non-haem iron.

Coulometric titrations<sup>17</sup> (Fig. 2) reveal a reversible Nernst plot (for  $n = 1$ ) with a potential of  $-416$  mV at pH 7 using methyl viologen as the mediator. Coulometry shows that for most samples one electron is taken up for each iron atom present in the molecule. Spectroscopy reveals that both the haem and the large excess of non-haem iron are reduced in this process. Potentiometric titration of the protein, carried out by monitoring the appearance of the  $\alpha$  band of the reduced haem, reveals that the haem undergoes reduction at a potential only 30 mV more negative than that of the bulk iron. Thus, both the haem and non-haem iron are reducible at similar extremely low redox potentials. These potentials are significantly more negative than those required to reduce horse spleen ferritin.

We have preliminarily explored the fate of the reduced *Azotobacter* protein. Our initial experiments show that the coulometrically fully reduced protein can be passed through an

**Fig. 2** Coulometric titration of bacterioferritin-cytochrome of *A. vinelandii* at 25 °C and pH 7 versus the normal hydrogen electrode using methyl viologen as mediator by the method described in ref. 12. The points are experimental values and the curve is calculated from the Nernst equation for  $n = 1$ ,  $E' = -416$  mV.

**Table 1** Comparison of *Azotobacter* protein with horse spleen ferritin

Aminoacid	<i>Azotobacter</i> bacterioferritin-cytochrome	Horse spleen ferritin
Cys	2.3	2.9
Asx	17.2	17.3
Thr	2.2	5.5
Ser	5.3	9.0
Glx	26.8	23.9
Pro	2.3	2.8
Gly	9.9	9.9
Ala	8.0	14.0
Val	1.9	6.9
Met	4.4	2.8
Ile	12.2	3.5
Leu	25.7	25.0
Tyr	5.7	5.0
Phe	2.1	7.3
Trp	2.4	2.1
His	6.9	5.8
Lys	11.7	8.7
Arg	3.1	9.5
Subunit MW (SDS gel electrophoresis)	17,000*	18,500

The analysis of *Azotobacter* bacterioferritin-cytochrome was carried out on protein samples without Fe removal. Similar analyses to those shown here on this protein by D. Jacobs and the late W. A. Bulen (D. Jacobs, personal communication) give values which differ from those reported here by less than a single residue for each amino acid. Data for horse spleen ferritin are from ref. 6.

\*Obtained by the procedure of Weber, Pringle and Osborn<sup>30</sup> using, as calibrants, aldolase, pepsin, chymotrypsin, trypsin, ferritin, myoglobin, haemoglobin, lysozyme and cytochrome *c*.

anaerobic Biogel P-2 column such that >90% of the (ferrous) iron is maintained in the reduced protein, which elutes with the solvent front. Separate experiments demonstrate that the column easily separates reduced ferritin-cytochrome from added ferrous ions. The eluted fully reduced ferritin-cytochrome can then be rapidly reoxidised by air to a species which is spectroscopically and analytically indistinguishable from the original oxidised material, with the exception of a small loss of Fe. The *Azotobacter* protein seems to hold its iron longer in the reduced state than does mammalian ferritin.

We conclude that *A. vinelandii* produces a protein with dual bacterioferritin-cytochrome character. If the molecule resembles ferritin in quaternary structure (as seems likely from the electron microscopy), then its 24 subunits, ~12 haems and average of 1,600 Fe atoms in the oxide-hydroxide-phosphate core give a material of MW 660,000 capable of taking up or delivering up to 1,600 electrons. It differs from mammalian ferritin in that it contains haem, has a lower redox potential and holds its iron more tenaciously in the  $Fe^{2+}$  state. We can only speculate on the physiological function and biological ubiquity of this bacterioferritin-cytochrome.

The high iron content makes this protein a prime candidate for an iron storage protein of *A. vinelandii*, much as ferritins have this function in mammalian, plant and fungal systems<sup>1-3</sup>. If Fe storage is indeed its physiological role, then, as has been postulated in mammalian systems<sup>18-21</sup>, iron mobilisation may be effected by the reduction of  $Fe^{3+}$  to the more labile and more soluble  $Fe^{2+}$  state. Perhaps the presence of the haem in the same molecule facilitates the reduction of the internal ferritin Fe. Why, then, is such a low potential required to mobilise the Fe? An intriguing hypothesis is that the Fe in the ferritin-cytochrome is a specific iron-storage depot for nitrogenase and its low redox potential ensures that only when the local redox potential in the cell approaches the negative values required for nitrogenase turnover (~-430 mV)<sup>22</sup> will the iron be mobilised from the ferritin-cytochrome.

An alternative or possibly additional role of the bacterioferritin-cytochrome involves its functioning as an electron storage

protein. The ability of this single molecule to take up hundreds of electrons at a low redox potential suggests that in *Azotobacter* this protein may function to supply low potential redox equivalents for use in respiration, biosynthesis or nitrogen fixation.

Many bacteria<sup>23</sup>, including *Azotobacter*<sup>24</sup>, excrete siderophores in conditions of Fe deficiency. It seems likely, therefore, that in conditions of iron sufficiency, species other than *A. vinelandii* will also have developed the ability to make bacterioferritin. Furthermore, some of these bacterioferritins could contain haem as does the *Azotobacter* protein. Spectroscopically, the haem absorptions found in the *A. vinelandii* protein are extremely similar to those found in cytochromes *b*<sub>1</sub> (often of unknown physiological function) from various bacterial sources<sup>25</sup>. Although none of the other cytochromes *b*<sub>1</sub> have been reported as containing non-haem iron, these do share with the *A. vinelandii* ferritin-cytochrome a relatively low redox potential and a tendency to be present in high MW aggregates. As cytochrome *b*<sub>1</sub> purification procedures often involve the use of detergents (which would cause loss of Fe<sup>3+</sup> core and leave apoferritin), the possibility remains that these are the bacterioferritin-cytochrome analogues of apoferritin.

In mammalian Fe metabolism, a close relationship between ferritin and haem metabolism has been postulated in mitochondrial particles, and evidence for direct involvement of ferritin in haem biosynthesis has been considered<sup>26-29</sup>. Further studies of bacterioferritins and/or bacterioferritin-cytochromes may help to establish evolutionary links which could improve our comprehension of both microbial and mammalian iron metabolism.

We thank Deloria Jacobs and Sam Lough for assistance in protein preparation and manipulation, Dr Harry E. Calvert for the electron microscopy, Dr Kenneth F. Miller for the magnetic susceptibility studies and Drs George Lang and Kevo Sparalian of The Pennsylvania State University for informing us of the Mössbauer spectroscopy results. The amino acid analysis of *Azotobacter* bacterioferritin-cytochrome was carried out by AAA Laboratory, Mercer Island. The whole experiment is contribution 647 from the Charles F. Kettering Research Laboratory.

## Structure of the iron-sulphur clusters in *Azotobacter* ferredoxin at 4.0 Å resolution

A FERREDOXIN-LIKE protein from *Azotobacter vinelandii* having 6-7 Fe and 6-7 S<sup>2-</sup> per mol and a molecular weight of 14,000 has been described by Shethna<sup>1</sup> and Yoch *et al.*<sup>2</sup>. Its biochemical properties<sup>3</sup>, electron paramagnetic resonance and redox behaviour<sup>4,5</sup>, and primary sequence<sup>6</sup> have also been studied. This work has established that there are two Fe-S centres separated by 0.744 V in reduction potential, one behaving like the [Fe<sub>4</sub>S<sub>4</sub>S<sub>4</sub><sup>2+</sup>] cluster in high-potential iron proteins, the other displaying novel characteristics. The distribution of cysteines in the N-terminal sequence is distinctly non-homologous with clostridial ferredoxins. Extrusion of the Fe-S cores by thiol displacement produces unique species, suggesting the presence of a new chromophore structure<sup>7</sup>. I report here crystallographic studies of the protein in a tetragonal crystal form which have led to an electron density map at 4.0 Å resolution. This map reveals two Fe-S clusters of clearly different size and shape. It has not been previously shown that this Fe-S protein, or any other, actually contains clusters of differing structure.

The protein was isolated by the method of Shethna<sup>1</sup> ( $A_{280}/A_{400} = 1.7-1.8$ ) and crystallised as square bipyramidal prisms<sup>8</sup>. The crystals are tetragonal, space group P4<sub>3</sub>2<sub>1</sub>2 with  $a = 55.24$  Å,  $c = 95.05$  Å, and one molecule per asymmetric unit. Diffractometer data have been collected to 4.0 Å resolution from single crystals of the native and an isomorphous derivative prepared with K<sub>2</sub>PtCl<sub>6</sub>. Data were collected at 10 °C using CuKα radiation and an  $\omega$  step-scan procedure. Bijvoet pairs were measured at  $\pm 2\theta$  in blocks of 10 reflections. After 6 d of irradiation, decay at 4.0 Å was 20%.

Table 1 Single isomorphous replacement phase sets

Phase Set	Space group	Pt			<i>E</i>	<i>R</i> <sub>c</sub>	$\langle m \rangle$
		<i>x</i>	<i>y</i>	<i>z</i>			
1	P4 <sub>1</sub> 2 <sub>1</sub> 2	0.48	0.13	0.19	33.3	0.478	0.49
2	P4 <sub>1</sub> 2 <sub>1</sub> 2	-0.48	-0.13	-0.19	38.9	0.552	0.47
3	P4 <sub>3</sub> 2 <sub>1</sub> 2	0.48	0.13	0.19	39.4	0.547	0.47

for 475 centric reflections (0*kl*, *hk*0, *hhl*).

$\langle m \rangle$ , Mean figure of merit.

**Fig. 1** Electron density map of *Azotobacter ferredoxin*. Fe-S clusters are marked A, B. Seven sections on  $x$ , 0.23–0.35;  $y$  axis vertical, 0.18–0.52;  $z$  axis horizontal, 0.23–0.43. Grid spacing  $\sim 1.9$  Å. Contours start at 18% of highest density (cluster A) with intervals of 10%.

The isomorphous difference Patterson map for the derivative showed six peaks (average peak to background ratio 3:1) consistent with a single major Pt site. Patterson maps using data from three additional Pt-soaked crystals in trial experiments were similar. The correct hand of both the heavy atom position and the space group was determined unambiguously by using the anomalous scattering from iron. Four protein phase sets were derived using the Pt data without anomalous dispersion (Table 1). In each case Bijvoet difference<sup>9</sup> and 'best' Fourier maps were computed using the native data. Phase set 1 yielded two large positive peaks in the 'best' Fourier at the Fe-S cluster sites, but large negative peaks at these sites in the Bijvoet difference map. Phase sets 2 and 3 produced uninterpretable maps. With phase set 4 both Fourier maps contained large positive peaks at the Fe-S sites at positions related by  $1/2-z$  from the set 1 maps, establishing this as the correct enantiomer. Subsequently, the heavy atom parameters and protein phases were refined in  $P4_32_12$  with Pt anomalous data included (Table 2). Difference Fourier maps revealed no secondary Pt binding sites. A Bijvoet difference Fourier with Pt anomalous differences again showed positive peaks at the Fe-S sites as well as a peak at the Pt site, the highest in the map and more than twice as high as the Fe-S peaks.

The electron density map in the region of the Fe-S clusters is shown in Fig. 1. The clusters are separated by 11 Å and occur at 0.26, 0.39, 0.38 (A) and 0.30, 0.28, 0.28 (B). Several stretchings of the polypeptide chain can be traced in the native map, including a right-handed helical segment. A clear solvent boundary delineates a molecule  $30 \times 25 \times 35$  Å in size. The map is featureless at the Pt site, which occurs on the molecular surface 19 Å and 13 Å from clusters A and B, respectively.

**Table 2** Refinement parameters for  $K_2PtCl_4$  derivative to 4.0 Å

$A^*$	62.88	$f_H$	126.8
$x$	0.4816	$E$	45.7
$y$	0.1352	$R_c$	0.478
$z$	0.3155	$\langle m \rangle$	0.66
$B$	28.00 Å <sup>2</sup>	$n$	1416

\* Occupancy on scale of  $f_H$ ,  $E$  (see Table 1 for definitions).

The most striking feature of the electron density is the differing shape and weight of the Fe-S peaks. Cluster A is essentially a 6 Å diameter sphere, consistent with the expected presence of a  $[Fe_4S_4S_4^{Cys}]$  cluster(s), like those seen in *Pepto-*

*coccus aerogenes ferredoxin*<sup>10</sup> and high-potential iron protein<sup>11</sup>. Cluster B, however, is significantly flattened and oblate in shape, being at most 4.5 Å thick. The maximum density at its centre is 75% that of cluster A. At 5.0 Å resolution, this cluster has a similar appearance but is only 55% the height of cluster A. Density maps calculated with centric or acentric phases only also give the same image of the Fe-S clusters. Thus, the electron density cannot be interpreted in terms of a second  $Fe_4S_4$  cube. Although it is not possible to distinguish unequivocally between other possible structures at this resolution, the density for the smaller cluster does suggest a two-iron centre, in analogy with model compounds of the type  $Fe_2S_2(RS)_4$  (ref. 12). This interpretation is supported by the fact that the protein chains attach to cluster A from several directions (two shown in Fig. 1), whereas cluster B is attached only at opposite ends.

A 4Fe-2Fe model agrees with the original Fe and  $S^{2-}$  assay and is consistent with the sequence. As the crystals diffract to 2.0 Å, the resolution of this study is being extended to resolve the Fe atoms and to trace the entire polypeptide chain.

This work is supported by a grant from the NIH (GM-25672). Diffractometer and computer programs were supplied by Drs R. McClure, J. Abola and M. K. Wood.

**Note added in proof:** W. V. Sweeney has recently determined by flame emission spectroscopy and colorimetric analysis using 1,10-phenanthroline that *A. vinelandii ferredoxin I* contains six atoms of iron per molecule, based on an extinction coefficient at 400nm of  $27 \text{ mM}^{-1} \text{ cm}^{-1}$ .

## Solar energy boom

D. O. Hall

*Solar Energy: The Awakening Science.* By D. Berham. Pp. 379. (Routledge and Kegan Paul: London, 1979.) £8.95.

WITH worldwide government-sponsored research and development on solar energy in 1979 approaching  $1 \times 10^6$ , it would be very worthwhile for anyone interested in solar energy, however remotely, to read this book. It provides an excellent and well written background to the technologies and personalities of those who have developed and are currently participating in the solar energy boom around the world.

As the United States has the largest and longest running government solar energy budget, about half the world total, its solar energy scene naturally occupies the majority of the book. However, the French solar energy scene is given wide coverage, as they have the third largest programme in the world and have had a sustained effort for many years. Unfortunately the very large Brazilian bio-fuels programme ( $\$300 \times 10^6$  per year) is not dwelt on; nor is the large Saudi Arabian programme ( $\$25 \times 10^6$  per year) nor the other Arab solar energy programmes which are also large. The German solar energy effort is also not discussed, even though their R & D budget is over  $\$30 \times 10^6$  per year; and like the French they have substantial government tax incentives for industries and individuals to install solar energy devices. The United Kingdom solar energy effort (government R & D spending  $\$3 \times 10^6$  per year and no tax incentives) commands a whole chapter. We are credited with having "the thread of originality" (a passively heated school near Liverpool, built in 1961) but "certainly do not believe in trying to solve the problem of solar energy by throwing money at it"—does this sound familiar?

I can thoroughly recommend this book. I read it from cover to cover in a short time but I am probably too interested in solar energy so as to be termed "unusual" or other less kindly epithets. The background work and interviewing which the author (a science writer for UNESCO in Paris) obviously put into the writing of the book comes across clearly. The technical details are kept to a minimum,

and the explanations of the various solar energy systems now operating, or on the drawing board, for houses, factories, swimming pools, satellites, power towers, farms, and so on, are remarkably lucid. It is therefore good for all sections of the community who want to find out what is behind all the jargon which inevitably seems to accompany a technical field. Sometimes one wished for less snippets about the motels and meals and even more about some of the personalities, but the personal flavour of writing is attractive—don't be put off by the first two or three pages (unless of course you like Brittany!) A truly excellent index provides a ready means of finding any topic, person, place, laboratory, company, committee, country (and so on) mentioned in the book. In fact just reading through the index gives one quite an overview of the varied interests and technologies in the field of solar energy.

The final chapter was completed in 1978 and gives an up-to-date view of the status of the implementation of

solar energy programmes in the USA—5,000 solar heated and 50,000 solar hot water houses ( $\$30 \times 10^6$  annual market) with a projection of  $2.5 \times 10^6$  solar heated houses by 1978 ( $\$1 \times 10^9$  annual market). The State of California could not wait for the federal government (which at the end of 1978 offered tax credits up to \$2,200 for each solar energy installation) and became the first State to offer generous incentives—"home owners get a tax credit of 55% up to \$3,000 on a purchase and installation of a solar energy system. Businesses are also given a 25% tax credit if their systems cost more than \$6,000".

The author is not a starry-eyed "solar nut", as he asks searching questions, expresses many doubts throughout the book, and rightly stresses energy conservation techniques right from the start. □

## Medicinal botany

*Healing Plants: A Modern Herbal.* Edited by W. A. R. Thomson. (Macmillan: London, 1978.) £9.95.

Up to a few years ago very few books on medicinal plants had been written this century for the layman, certainly in English. There was Mrs Grieve's *A Modern Herbal*, published in 1931, as well as some charming if rather less practical books by E. S. Rohde, which came came out about the same time. Mrs Grieve's work covers a wide range of plants, is packed with information, much of which is difficult to find elsewhere, and is a sensible, down-to-earth publication even if it does not contain much information on the chemical constituents of plants (a great deal of work has been done on this in the past fifty years). Nevertheless, I think that when reviewing new books on medicinal plants it is fair to use Mrs Grieve as a standard by which to judge them. The kind of people who will buy and use these new books are probably the same kind as those who bought and

used *A Modern Herbal* in the 1930s.

There seems to be a much wider interest in medicinal plants now than was common even ten years ago. This is no doubt partly a spin-off from the ecology movement but is also the result of the related desire for a simple life, especially among townspeople. Whatever the basis for this interest, it is illustrated by the increase in health food stores selling herbal remedies for a wide range of afflictions. The market for books on medicinal plants is provided with an ever-increasing flow of works of varying merit. The one reviewed here is a typical example and like the curate's egg may be described as good in parts. To start with, it is very attractive to look at; the illustrations—both colour photographs and reproductions of old botanical drawings—are on the whole excellent, as is the printing. But I found the matter contained in the book (and its layout) rather disquieting.

The book is divided into a number of alphabetical lists interspersed with chapters on healing plants and their

active principles, the heritage of folk medicine, and so on. A list is provided of plants under English common-names—not always correct—with the conditions they are held to alleviate; and under latin names with an illustration and general description that would not be very helpful to a non-botanist, and is followed by a list of complaints and illnesses, with the plants used. This list unfortunately does not always tally with the first and is followed by yet another on healing substances and their effectiveness. This last list is about the parts of the plants used, their constituents, and how they are processed. It is the most informative of the sections, but would be more helpful if sources

of both herbal and planting material were given. For example, Asiatic ginseng is listed, but where the authors' expect would-be growers to buy planting material I do not know; so far as I am aware it is only available from Japan. The book would have been far more useful if the information on each plant were all in one place, instead of being scattered throughout. Lists of suppliers—both of the dried herbs and of planting material—would have increased its value enormously. Once again Mrs Grieve wins overall.

## Plant breeding for disease resistance

*Plant Breeding for Pest and Disease Resistance.* By G. E. Russell. Pp. 485. (Butterworths: London, 1978.) £25.

DURING the past few years, radical changes have taken place in the strategies used by plant breeders when breeding for resistance to plant pests and diseases. Following the discovery by Biffen in 1907 that resistance to a disease was often conferred by a single gene, known as a major gene, many plant breeders used small numbers of major genes to obtain resistance. It was subsequently found, however, that resistance based on a single major gene, or a few such genes, frequently broke down within a few years of its introduction into a crop plant, due to the pathogen producing new races capable of overcoming that gene. G. E. Russell has been actively concerned in devising new breeding strategies designed to provide durable resistance, and this book reflects his experience and methods of approach.

The first part of the book is devoted to a brief but useful summary of methods used for the control of plant diseases, and to a consideration of the general principles and methods of breeding for resistance. The technical terms and concepts used in plant breeding are clearly defined: though some might not agree with all the definitions offered, they are clear and unambiguous. There is a valuable section on methods, many developed by the author and his colleagues, for the introduction of resistance into commercial crops, and for its assessment when introduced.

Parts II to V are devoted to breeding for resistance to specific groups of pathogenic agents, namely the fungi,

the bacteria, mycoplasmas and viruses, animal pests and parasitic weeds. In each part, a general introduction is followed by a detailed treatment of a few selected cases in each of which substantial progress has been made in the production of resistant cultivars of crop plants. These case histories fulfill two main functions. For the specialist student, they provide a good and usually up to date account of the present position, with adequate references to the literature. For the more general reader, they illustrate very clearly the ways in which the general principles advocated by the author can be applied to obtain durable resistance to almost any type of pest or disease, with modifications in detail rather than in principle to fit any specific case.

In the final part of the book, some general conclusions on the present position and future prospects in the field are set out. The author is hopeful that by the use of major genes, where they are proved to be durable, and by the use of more sophisticated approaches where they are not, it will be possible to control many major pests and pathogens. The casual reader may at first get the impression that it is suggested that breeding is the only satisfactory solution to pest and disease problems, but in the final section, the author is careful to emphasise that in many situations an integrated control programme involving both resistant cultivars, pesticides and biological and cultural control methods may be required.

This book is a very useful addition to the literature of plant breeding and plant pathology. It will be of value both to the student entering this field, and to the more general reader who is seeking an insight into the principles and methods of modern disease and pest resistance breeding.

## Applying digital filters

*Digital Filters and their Applications.* By V. Cappellini, A. G. Constantinides and P. Emiliani. Pp. 393. (Academic: London, New York and San Francisco, 1978.) £20.50; \$42.

THE appearance of this volume in a series on *Techniques in Physics* is something of a landmark, for it is only recently that filters have ceased to be studied almost exclusively by electrical engineers, and written about for readers with formal training in that field. The intensive study of two-dimensional filters is also a recent development, spurred on by the need to clean up satellite pictures and by a variety of biomedical and geological needs. In connection with these and related applications, many scientists with no engineering background have been using—and rediscovering—filters to improve their "signals", and the present authors have therefore attempted to compose a text that would appeal to such an audience as well as to engineers. This is no easy task, for the types of presentation likely to satisfy these two categories of reader are rather different, particularly in the handling of mathematical details and in the need to put the material under discussion in context. The solution adopted by the authors, who present a great deal of material with very little comment or explanatory text to help the reader to assimilate it, is not at all satisfactory. It is certainly possible to look up any number of facts about filters, both FIR and IIR, their software and hardware implementations and noise, but it is extremely difficult to get any feel for their power or suitability. The section entitled "Description of some windows" is an example of this: two formulae tell us how to distinguish a Hamming window from a Hanning window but not why two nearly identical windows should coexist. The formulae for numerous other windows are also given, sometimes with some indications about their origin but not always.

This is a disappointing book, therefore, except as an *aide-memoire* for finding formulae and definitions. The authors' object was certainly laudable but for the time being the pair of books on digital signal processing by Rabiner and Gold and by Oppenheim and Shafer (Prentice-Hall, 1975) remain the most useful source of information on these matters.

**P. W. Hawkes**

*P. W. Hawkes is Maître de Recherches at Laboratoire d'Optique Electronique du CNRS, Toulouse, France.*

## Vibrational and electronic spectroscopy

*Symmetry and Spectroscopy: An Introduction to Vibrational and Electronic Spectroscopy.* By M. C. Harris and M. D. Bertolucci. Pp. 550. (Oxford University Press: New York, Oxford and London; 1978.) £15.

A NEW textbook dealing with vibrational and electronic spectroscopy, at third-year undergraduate level, with group theory as the unifying thread, has been needed for some time. This ambitious book goes somewhat further into spectroscopy than I would expect third-year undergraduates to go, from foundations which are not quite deep enough.

The book is ambitious because it aims to be self-contained, assuming little background knowledge (except some quantum mechanics). This has meant difficult decisions as to which theoretical results to explain, which to assume and which to ignore. The first chapter is an extremely readable account of groups and representations which deliberately ignores the theorems

of representation theory (the four rules) and simply states the key result, the formula for decomposing a representation, by *fiat*. The relationship between group theory and the Hamiltonian is not discussed: the student who wishes to know why molecular eigenstates necessarily have symmetry properties must look elsewhere, or simply accept that normal coordinates and molecular orbitals transform as irreducible representations. Without making the book longer, much of this theory could have been included at the expense of chapter two, a sketch of quantum mechanics which adds little to the book and incidentally contains an incorrect interpretation of the superposition principle.

The theory of molecular vibrations and of molecular orbitals provided here is rather elementary compared with the level of the spectroscopy which follows. A verbal definition of a normal coordinate without the equations of motion does not indicate clearly what a normal coordinate is, nor why it can sometimes be determined by symmetry. Similarly, without some idea of an effective one-electron potential, one cannot properly explain the Koopmans theorem nor insist that the molecular orbitals have symmetry properties.

Hückel theory is presented here without any suggestion that the Hamiltonian is not the total molecular Hamiltonian.

Most of the above criticism assumes the educational importance of principles in themselves. Of equal if not more importance for the specialist is the application of principles in puzzle-solving; and it is here that the authors have succeeded brilliantly. Interwoven with the text are many examples of spectra (very well illustrated) from the literature and over 200 problems. The student who completes even a modest fraction of these problems should be able to construct symmetry coordinates and orbitals, determine the states which arise from electronic configurations, and decide which transitions are allowed. In short, he should be able to read the literature of vibronic spectroscopy. The theoretical aspects of this book could easily be supplemented by a lecture course. The strengths of the book lie precisely where formal lectures are often weak—in examples—and for this reason both teachers and students will find it valuable.

M. P. Melrose

M. P. Melrose is Lecturer in Theoretical Chemistry at King's College, University of London, UK.

## Fundamental research in gerontology

*The Biology of Ageing.* Edited by J. A. Behnke, C. E. Finch and G. B. Mowbray. Pp. 388. (Plenum: New York and London, 1978.) £11.93.

AGEING is the next growth industry, perhaps hardly surprising in Western Societies, as two of the three major scourges—famine and pestilence—have been controlled, and the third—war—is unacceptable, at least in theory. About 1 in 6 of our population is over 65. In the United States there are now 22 million people over 65 and early in the next century this figure is expected to increase to 50 millions. Little wonder that the young who have to support the more elderly amongst us are becoming concerned. What do they do with this rapidly increasing army of non-productive geriatrics—parasites on a society which they have helped to build?

Unfortunately, this book does not consider the social problems of ageing but it does deal with most other aspects. It is intended for a general audience but a good knowledge of modern biological theory is an essential prerequisite.

The contributors review most areas of interest in fundamental research in gerontology, particularly ageing in cells and molecules, and ageing in plants and lower animals, but there are also substantial sections on ageing in man and on the effects of hormones on ageing. The book concludes with a section on perspectives. As with any book with 25 contributors, the individual articles vary in quality. Some can be read with pleasure, others are rather heavy going, but all provide good background information and each gives a useful reference list for further reading.

Although ageing and death are the inevitable end-results for most metazoa, we still know very little about the mechanisms involved. It is perhaps the most intellectually challenging problem in biology, yet research on ageing forms only a very small part of the major research programmes. Few universities or medical schools consider ageing to be a basic biological process of sufficient importance to form the basis for organised courses.

This book provides an excellent basis for an introduction to modern research on ageing, but it may be somewhat too detailed to serve as a course book.

L. M. Franks

L. M. Franks is Head of the Department of Cellular Pathology at the Imperial Cancer Research Fund Laboratories, London, UK.

## John Maddox

Croom Helm wish to apologise to Mr John Maddox for the reference to him in connection with recombinant genetics in their book *Directing Technology*. The publishers (Croom Helm) and the Editors (Ron Johnston and Philip Gummert) and the author of the chapter concerned (Dr Edward Yoxen of the Department of Liberal Studies in Science at the University of Manchester) unreservedly withdraw any suggestions of impropriety in Mr Maddox's role in public discussion of this issue.

## High performance liquid chromatography

*Applications of High Performance Liquid Chromatography.* By A. Pryde and M. T. Gilbert. Pp. 255. (Chapman and Hall: London, 1979.) £10.50.

THE authors of all compilations of the applications of any analytical chemical technique have to contend with two basic problems. In the first place only a very small part of the text will be of direct interest to any particular reader, and secondly in the case of any rapidly developing method such as high performance liquid chromatography (HPLC), there is a danger that much of the described methodology will be outdated even during the time required for publication.

The present authors have skilfully avoided both these pitfalls, the first by confining their main coverage to three fields of wide general interest—pharmaceutical analysis, biochemical analysis and methods for monitoring environmental pollution. Some other miscellaneous topics are also treated briefly. The second problem—of current relevance—has been met by providing a very complete review of the literature up to Spring, 1977. Publication delays being what they are at present, this must be considered very good.

A very short but good summary of the relevant theory, a similarly brief account of the currently available instrumentation, and a more extended and valuable section on the practice and principal modes of operation of HPLC lead into the major sections of the book.

Within the selected topics the coverage provided is excellent. For example, the 48 pages devoted to pharmaceutical analysis includes most of the classes of drugs now in general use, from antibiotics to diuretics (including a section on analysis for drugs of abuse). In many cases examples of methods of HPLC analysis for the drug metabolites are included.

The major 61-page section on applications of HPLC to biochemical analysis is particularly thorough, and includes sub-sections on lipids (including steroids and prostaglandins), polycarboxylic acids of metabolic importance, carbohydrates, biogenic amines, amino acids and proteins, nucleic acid derivatives porphyrins, and the common vitamins. It is very encouraging to find some space devoted to HPLC of proteins, as in my view the HPLC of biological macromolecules has lagged behind the much easier HPLC of small

molecules, many of which can readily be fractionated by easier (and much cheaper) methods. The intrinsically high resolution of HPLC methods should be particularly valuable for the separation of large nucleic acid and protein fragments (or even subunits) which are required for the sequencing of the intact molecules.

The brief sections on applications of HPLC to environmental monitoring and various miscellaneous separations, including stereoisomers, provide adequate coverage for their purpose.

The book concludes with a series of appendices listing in considerable detail various types of packings for HPLC columns, and finally with a very use-

ful specific index of compounds mentioned in the text, which greatly enhances its value as a reference book. The scope of this very useful book is illustrated by the 876 quoted references, mostly subsequent to 1970. The production of the book is excellent at its price, and there are very few misprints, although I found the use of the word "colourimetric" throughout the book mildly irritating.

C. J. O. R. Morris

C. J. O. R. Morris is Emeritus Professor of Experimental Biochemistry, formerly at the London Hospital Medical College and Queen Mary College, University of London, UK.

## Molecular photoelectron spectroscopy

*Photoelectron Spectroscopy and Molecular Orbital Theory.* By R. E. Ballard. Pp.192. (Adam Hilger: Bristol, 1978.) £18.

THE author of this book has appreciated the value of molecular photoelectron spectroscopy as a teaching aid in chemistry. Other books on the subject have tended to emphasise its contribution to the advancement of knowledge and have been directed primarily at researchers. He recalls the late Professor C. A. Coulson's remark about the impact of photoelectron spectroscopy: "The single result of most significance is the complete vindication of the molecular orbital description of a molecule". Molecular orbital theory is taught throughout university chemistry schools, sometimes with the clarity which the late Professor Coulson used to demonstrate, all too often, however, as a beautiful mathematical theory; that in some ways is good for the undergraduates to master, but which many find sterile because of an over-emphasis on exactitude. The aim of the present book clearly is to demonstrate that photoelectron spectroscopy and especially helium I photoelectron spectra of vapours have an important part to play in introducing undergraduates rather painlessly to some of the essential concepts of molecular orbital theory.

In order presumably not to overburden the student, a number of topics which a specialist would think essential have been omitted; notably no discussion is given of the interpretation of spectra based upon ionic states, to which reference must always ultimately be made. The author is content to emphasise only the relationship between occupied orbitals and the

bands in the photoelectron spectra. This is attempted by assembling the spectra for a rather limited range of simple molecules falling into groups of increasing complexity and then discussing these in some detail. These comparative chapters are preceded by a more general introduction to the necessary molecular orbital concepts. Some use has been made in the comparative chapters of the computer-generated drawings of Jorgensen and Salem (*The Organic Chemists' Book of Orbitals*, Academic: New York, 1973) to provide an insight into the geometrical factors which are often implicit in the details of the photoelectron spectra. This is often a most revealing juxtaposition and the reviewer feels that even more use could have been made of this to advantage. The detailed comparisons are quite restricted in their coverage, ranging from diatomics, through triatomics, molecules related to ethylene, and some tetrahedral and octahedral molecules. Within these groupings are, however, to be found a number of examples of substances whose electronic structure will have been a puzzle at one time or another to most chemistry undergraduates.

The importance of the finer detail in the spectra is not treated in depth. The section on vibrational fine structure is perhaps less well illustrated in certain respects than other areas, both with regard to selection of examples and more particularly the quality of reproduction of some of the spectra. In this area in particular spectral resolution and the fineness of detail which can be read into many spectra are of fundamental importance; their proper discussion requires both well reproduced examples and a proper treatment of the concept of the ionic state manifold, which, as remarked above, is a significant omission.

## BIOCHEMISTRY

### ANTIMETABOLITES IN BIOCHEMISTRY, BIOLOGY AND MEDICINE

Proceedings of a symposium on Antimetabolites in Biochemistry Biology and Medicine, Prague, Czechoslovakia, July 10 – 12, 1978

FEBS Volume 57

Editors: J. SKODA AND P. LANGEN, Prague, Czechoslovakia

Previously, most literature concerning antimetabolites has been approached from a pharmacological viewpoint. The aim of this symposium was to stress the many applications of antimetabolites, both as research tools and for their chemotherapeutic use. As such, it will be of great interest to researchers and practitioners in many areas of biology and medicine.

### PLACENTA—A NEGLECTED EXPERIMENTAL ANIMAL

Proceedings of a Round Table Discussion held at Bedford College, University of London, October 1978, under the auspices of the Special Commission on Internal Pollution

Editors: PETER BEACONSFIELD, London, UK  
CLAUDE VILLEE, Harvard University, USA

This volume discusses the best possible use of the unique and remarkable attributes of the placenta, in order to apply it to the study of physiopathological processes such as cell replication (normal and abnormal), immunological processes, ageing, metabolism and drug effects.

The value of this book lies in the discussion section which looks to possible pointers for the future study of physiopathological processes.

## FOOD SCIENCE

### SINGLE CELL PROTEIN – SAFETY FOR ANIMAL AND HUMAN FEEDING

Proceedings of the Protein-Calorie Advisory Group of the United Nations System Symposium, held at the Istituto di Ricerche Farmacologiche, 'Mario Negri', Milan, Italy, March 31 – April 1, 1977.

S. GARATTINI et al

The aim of the book is to provide to scientists, technologists and government administrators the best recent information concerning the safety for human and animal consumption of single-cell proteins, which at this time are primarily yeasts cultured on a variety of substrates. It should be useful as a textbook for courses on world food resources, industrial microbiology, livestock feeding and food safety and nutritional quality.

### MEAT SCIENCE 3rd Edition

R.A. LAWRIE, University of Nottingham, England

A revised and enlarged edition of a popular textbook for food science and food technology students. Recent basic discoveries on the attributes of the eating quality of meat and descriptions of the means which permit control over them in industrial practice are incorporated. Meat Science is based on many years' experience of the subject by an acknowledged world expert who is personally acquainted with the topics described.

### THE CILIATED PROTOZOA 2nd Edition Classification and guide to the literature characterization.

J.O. CORLISS, University of Maryland, USA

A unique reference work providing documented revision of the overall classification of the expanding protistan phylum Ciliophora, based on new data in comparative taxonomy and on fresh hypothesis concerning the phylogeny and evolution of these microorganisms. A comprehensive and authoritative reference work for all involved in cell biology, ecology and pollution biology, as well as protozoology, parasitology and invertebrate zoology.

### THE CONTROL OF GROWTH AND DIFFERENTIATION IN PLANTS \*2nd Edition

P.F. WAREING, University College of Wales, UK

I.D.J. PHILLIPS, University of Exeter, UK

A new edition of a popular textbook introducing the subject for undergraduate students. Large sections have been re-written to bring the information up to date, and an additional chapter on phytochrome and photomorphogenesis is now included. There is also an extensive re-arrangement of the material to give a more logical and coherent presentation.

## INSECT CLOCKS 2nd Edition\*

D.S. SAUNDERS, *University of Edinburgh, Scotland*

This volume is concerned with those phenomena in which 'environmental time' has a functional significance in the life of insects, enabling them to perform behavioural or physiological events at the right time of the day or year. It firstly considers the fundamental properties of circadian rhythms and continues with the largest sections on seasonal photoperiodism.

The concluding chapters compare other insect clocks, rhythmic and non-rhythmic, with the circadian system and describe what is known about the anatomical location of the circadian pacemakers and photoreceptors.

## KEEP OFF THE GRASS A Scientific enquiry into the biological effects of marijuana.

G. G. NAHAS, *Columbia University, USA*

At a time when strong forces in many communities are pressing for the legalization of Marijuana, most public information on the subject concerns Marijuana's impact from a legalistic rather than a scientific viewpoint. This book presents the truth about the many dangers of the drug from documented medical, pharmacological and scientific evidence, at a level which will be easily understood by those with little scientific background.

## THEORETICAL PHYSICS AND ASTROPHYSICS

V. L. GINZBURG, P. N. *Lebedev Physical Institute, Academy of Sciences of the USSR*, Translated by D. Ter HAAR, *Oxford University, England*

The first text on theoretical physics and astrophysical applications, this book covers many recent advances, including those in x-ray,  $\gamma$ -ray and radio-astronomy. It presents, on the one hand, various topics in theoretical physics in depth — especially topics related to electrodynamics and on the other hand, shows how these topics find applications in various aspects of astrophysics.

## PRINCIPLES OF POLLINATION ECOLOGY

Third Revised Edition\*

K. FAEGRI, *University of Bergen Botanical Museum, Norway*

L. VAN DER PIJL, *Sportlaan, The Hague, The Netherlands*

Approached from both a theoretical and a practical viewpoint, this survey presents examples from all geographical areas where pollination has been studied and general principles are illustrated by a number of concrete examples.

Introductory chapters survey the technical problems and draw comparisons with spore dissemination in cryptogams and pollination in gymnosperms. The following chapters deal with angiosperm pollination and are divided into three parts: organs involved in pollination, flower types and pollinator activities.

## DESCRIPTIVE PHYSICAL OCEANOGRAPHY

G. L. PICKARD, *University of British Columbia, Canada*

The latest revised edition of this introductory text has been updated with new material, diagrams and plates. SI units are used; an appendix relates these to older units.

### CONTENTS (partial):

- Ocean Dimensions
- Shapes, and bottom materials
- Physical properties of sea-water
- Typical distributions of water characteristics in the oceans
- Water, salt and heat budgets of the oceans
- Instruments and methods
- Circulation and water masses of the oceans
- Coastal oceanography

### APPENDIX: Units used in descriptive physical oceanography

## HIGHEST STANDARD OF QUALITY IN BIOLOGICAL REAGENTS FOR THE STUDY OF NUCLEIC ACIDS, SYNTHESIS AND PROCESSING.

PRICES		
<b>RIBONUCLEASE PHYL</b> (Cat. No. ERN-PHY) (RNase I) from Physarum Polycephalum This novel enzyme preferentially digests G, A and U residues allowing discrimination between C and U in RNA sequencing by the gel method	Free from other Ribonuclease and Phosphatase activities	145.00/100 units
<b>T4 POLYNUCLEOTIDE KINASE</b> (Cat. No. EPN-4) (RNase-free) Prepared from T4-infected RNase I <sup>-</sup> E. coli specifically labels 5'-OH termini of RNA and DNA chains. With this product kinase labelling of small quantities of large RNA's for sequencing is possible for the first time	Free of nucleases	75.00/100 units 315.00/500 units
<b>T4 RNA LIGASE</b> (Cat. No. ERL-4) (RNase and DNase-free) The enzyme is capable of adding single residues (in the form of pNp) to 3' termini of the RNA chains, allowing sequence analysis by the gel method. Ligase from RNase I <sup>-</sup> E. coli allows application of this approach to a variety of large RNA's species	Specific Activity 2000 units/mg Completely Free of RNase and DNase Activities	60.00/100 units 235.00/500 units
<b>TERMINAL TRANSFERASE</b> (Cat. No. ETT-C) (from calf thymus) Suitable for addition of polydeoxy-nucleotides to an appropriate primer, or a single addition of a nucleotide at 3' end to create products suitable for DNA sequencing (procedure for a single nucleotide addition is provided by request)	Specific activity 50,000 units/mg Completely free of DNase activity	98.00/500 units 195.00/1000 units
<b>ALKALINE PHOSPHATASE</b> (Cat. No. EAP-1) (from E. coli BL 15 RNase I <sup>-</sup> ) This preparation is free of any detectable RNase or DNase activities	Specific activity 140 units/mg	65.00/100 units 120.00/250 units
<b>DNA POLYMERASE I</b> (Cat. No. EDP-1) (Kornberg polymerase) From E. coli BL 15 For analytical and preparative purposes Suitable for nick translation of DNA in vitro	Specific activity 15,000 units/mg Free of DNase and Exonuclease III	155.00/250 units 275.00/500 units
<b>EXONUCLEASE III</b> Cat. No. EEX-III	Free of endonuclease I or II Not less than 35,000 units/mg	60.00/250 units 95.00/500 units

## A new approach in tissue culture

## PETRIPERM

a novel culture dish with gas permeable membrane as cellular support.

Additional advantages of the PETRIPERM membrane are:

- UV permeable 200 nm
  - Suitable for high power light and fluorescence microscopy
  - The membrane can be cut for cell cloning, electron microscopy, staining and documentation
  - Chemically resistant to acids, bases and organic solvents
- PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.

In the intact animal, the pH and the partial pressure of both oxygen and CO<sub>2</sub> of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO<sub>2</sub>, pCO<sub>2</sub> and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 25 μm thick membrane.

## Heraeus— Co<sub>2</sub>-Incubator B 5060 EK/CO<sub>2</sub>

# newly on the market

**Optical scanner.** The new Stahl Research optical scanner can scan biological microsamples with high accuracy. A resolution of  $0.2\text{ }\mu\text{m}$  per pixel over a  $50\text{-}\mu\text{m}$  field is attained, resulting in a grid of  $256 \times 256$  pixel images. The Model 502 image analysis optical scanning microscope system guarantees  $0.2\text{ }\mu\text{m}$  overlay reproducibility with each subsequent scan. The microprocessor controlled system utilises oscillating mirrors and PMT detection to achieve a  $s/n$  ratio better than 46 dB. Included is a high precision X-Y stage and provision is made for a host of image processing algorithms. **Circle No. 84 on Reader Enquiry Card.**

The Stahl Research optical scanner

**Multi-wavelength photometer for HPLC.** The Du Pont 860 absorbance detector is a compact UV/visible photometer designed for high sensitivity detection of chromatographically separated components that absorb light at the mercury emission lines in the 254 to 546 nm wavelength region. The device can detect sample components at picogram levels. Model 860 uses optical filters and a stable, low pressure mercury lamp source with a phosphor-coated tip. A two-position mounting permits easy conversion from 254 to 284 nm. The flow-cell design permits sensitivities to 0.002 absorbance units full scale. Sample absorbance is continuously displayed on a digital meter for visual monitoring and recording. **Circle No. 85 on Reader Enquiry Card.**

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.

**Infra-red detectors.** Plessey announces a new range of fast-response uncooled infra-red detectors designed for general purpose infra-red laser studies, where the detection of low power fast infra-red pulse chains is required. These new devices, designated the PLT 411F series, have as detector element a single lithium tantalate crystal which has high voltage but for maximum mean power handling capability a pyroelectric ceramic element can be offered.

**Circle No. 86 on Reader Enquiry Card.**

**Liquid scintillation system.** The Packard Tri-Carb 460C, is an advanced microprocessor-based liquid scintillation system which dramatically increases the quality of data that can be obtained in cancer research, disease prevention, genetics, microbiology and other life science investigations. It features an integrated video display showing test procedures and results, a system controller and a built-in printer to record information on a report form. The system can handle as many as 460 samples. It has cassettes, or rack-like carriers which hold up to 10 samples each.

**Circle No. 87 on Reader Enquiry Card.**

**Cellulose acetate electrophoresis system.** A purpose built cellulose acetate system that produces consistently good results for a wide range of clinical applications has been produced by Shandon. Applications include the separation, identification and quantitation of serum proteins, haemoglobins, haptoglobins and glycoproteins. The system incorporates a newly developed cellulose acetate membrane, Celagram II, which provides sharper separations and shorter running times than previous membranes and eliminates the need for a final sticky clearing bath.

**Circle No. 88 on Reader Enquiry Card.**

**Luteinising hormone assay.** The new radioimmunoassay kit for Luteinising Hormone (LH) in human serum, from Amersham Corporation covers the range  $0\text{--}300\text{ mIU ml}^{-1}$ . Good performance throughout the shelf-life (normally 4–7 weeks from date of shipment) of the kit is ensured by the use of ion-exchange paper to partially purify the tracer prior to each assay. The Amersham LH RIA kit has been clinically tested.

**Circle No. 89 on Reader Enquiry Card.**

**Luminometer.** LKB-Wallac is introducing a new instrument for luminescence measurements. The Luminometer 1250 is the basic instrument comprising the measuring chamber with detector and the electronics unit. The detector is a photomultiplier which gives the instrument high sensitivity. The spectral response covers both chemiluminescence and bioluminescence. Various output devices can be used with the 1250. LKB-Wallac can supply a digital display and printer unit or a potentiometric recorder.

**Circle No. 90 on Reader Enquiry Card.**

**Nanometre particle sizer.** The Coulter Nano-Sizer determines average particle size in suspensions and emulsions in the overall range  $0.04\text{--}3.0\text{ }\mu\text{m}$ . This, together with an index of the width of the size distribution, is presented typically within 2–4 min with no operator attention, calculation or calibration. The built-in micro-computer ensures that no calculations are required and alleviates the necessity for calibration. Results are absolute and are displayed digitally to three significant figures. Areas of application include paints, pigments, latices, pharmaceuticals, emulsions of all types, carbon blacks and other colloidal materials.

**Circle No. 91 on Reader Enquiry Card.**

The Coulter Nano-Sizer

**Ultrasonic pipette and glassware cleaner.** The Branson Sonifier ultrasonic pipette and glassware cleaner is a new accessory to the Sonifier cell disruptor product line. The cleaner, comprised of an ultrasonic generator and a stainless steel cleaning tank, provides fast, efficient cleaning of all sizes of pipettes, glassware, and other laboratory instruments. No pre-soaking is necessary and several cleaning solutions are available.

**Circle No. 92 on Reader Enquiry Card.**

**Audible radiation monitor.** The Radia-tron 'Bristol Bleeper', developed in conjunction with the Physics Department Bristol General Hospital, is a convenient and simple method for safeguarding personnel against ionising radiation. The 'Bristol Bleeper' is only slightly larger than a pen and slips easily into a pocket, where it is held firmly by the strong stainless steel clip. The monitor operates over a wide range of radiation energies. It operates continuously giving a bleep every 10 min for normal background radiation increasing, with dose rate, to a continuous tone when high radiation doses are present. Typical endurance is 1 year using readily available batteries.

Circle No. 93 on Reader Enquiry Card.

The Bristol bleeper

**Light pollution rejection filter.** Celestron now offers a series of LPR filters that make bright city, light-polluted skies, appear dark by rejecting radiation from mercury and sodium type lights. This will be of great value to the amateur astronomer who will be able to make deep sky photographs from sites in built-up areas.

Circle No. 94 on Reader Enquiry Card.

**Computing integrator.** The Spectra Physics SP4100 computing integrator is microprocessor controlled, has a full Alpha Numeric keyboard and LED display and an integral Printer Plotter. BASIC is standard in the SP4100 with extensive built-in programming which can be easily reprogrammed by the user. The most often used data reduction methods in chromatography are all preprogrammed in ROM (Read Only Memory) and can be implemented with just a few key strokes. Built-in BASIC programming capability allows the user complete flexibility to modify an existing data reduction method, format his own report or develop other custom applications. The printer plotter prints at 24 characters per second in black on white, and can 'chart reverse' to do X-Y plotting.

Circle No. 95 on Reader Enquiry Card.

#### Monoclonal materials for B cell studies.

Sera-Lab produce three monoclonal antibodies directed against sheep red cells. The antibodies have been produced by the hybrid myeloma technique of Kohler and Milstein and are serologically distinct belonging to the mouse immunoglobulin classes IgG<sub>1</sub>, IgG<sub>2</sub> and IgM. For workers involved in the separation of human B lymphocytes for tissue typing and histocompatibility tests prior to transplantation, two different sera are available directed against the HLA-DR markers. The antibody MAS 020 is a non-complement fixing antibody and can be used for the preparation of enriched B cell suspensions for subsequent typing using complement dependent sera. Serum MAS 019 is a complement-dependent serum directed against B cells, which can be used for separation methods and as a good positive control in cytotoxicity tests and similar reactions.

Circle No. 96 on Reader Enquiry Card.

**Block digester for wet digestion/oxidation techniques.** Techne Inc. have developed a block digester system designed for sample preparation prior to analysis of grain, food products, soil, water pollutants, chemicals etc. The block digester is an alloy block heater system designed to heat samples at temperatures up to 450 °C for wet oxidation or acid digestion of material for assay, particularly of protein by the Kjeldahl method.

Circle No. 97 on Reader Enquiry Card.

Techne block digester

**HPLC chromatographic packings.** Du Pont present Zorbax NH<sub>2</sub> columns and Zorbax bulk liquid chromatographic packings. Zorbax NH<sub>2</sub> is a multipurpose column that can be used for high performance separations under normal, reversed phase, and ion exchange chromatographic conditions. This polar bonded column expands the range of Zorbax applications to include separations of materials such as carbohydrates, organic acids, and other polar organic compounds, including preservatives, antioxidants and pesticides. Zorbax bulk liquid chromatographic packings are spherical with a diameter of 7-8 µm.

Circle No. 98 on Reader Enquiry Card.

**Fibre optic illuminator for stereo microscopes.** Reichert-Jung UK in conjunction with American Optical Corporation announce the model 11-80 Fibre Optic Illuminator suitable for use within stereo microscopes from any manufacturer. The 11-80 incorporates a quartz halogen lamp (colour temperature 3,400 K) and its output is directed at the specimen through self-supporting fibre optic light guides. Single and branched guides are available, permitting accurate pinpoint illumination of the specimen. The unit incorporates a fan for cooling and has a neat cable storage.

## APPOINTMENTS VACANT

### NATIONAL UNIVERSITY OF LESOTHO

Applications are invited for two posts of

#### LECTURER/SENIOR LECTURER

in the DEPARTMENT OF BIOLOGY. Preference will be given to candidates specialising in the fields of Genetics and Entomology, but the appointees will be expected to teach in related subjects as well as in their own specialities. The appointments will be on contract terms for limited periods of two to four years for expatriates in the first instance and appointees will be expected to assume duty by August, 1979. Salary scales: Senior Lecturer R7,473 to R8,433 per annum, Lecturer R5,493 to R7,527 per annum (£1 sterling equals R1.76). The British Government may supplement salaries in range £1,644 to £2,508 per annum (sterling) for married appointees and £570 to £1,410 per annum (sterling) for single appointees (reviewed annually and normally free of tax) and provide children's education allowances and holiday visit passages. Family passages: Superannuation: Appointees on contract terms receive 25 per cent gratuity in lieu of superannuation for the first two years of the contract, rising to 27½ per cent and 30 per cent for each subsequent and similar period of service. 15 per cent inducement allowance for expatriates not qualifying for any supplementation aid scheme. Accommodation is available at reasonable rentals. Baggage allowance. Education allowance. Vacation and study leave. Medical aid Scheme. Detailed applications (two copies) with curriculum vitae and naming three referees by June 18, 1979 to the Administrative Assistant (Appointments) N.U.L., Roma, Lesotho, Africa. Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address.

634(A)

### THE UNIVERSITY OF SHEFFIELD RESEARCH ASSISTANT DEPARTMENT OF PHARMACOLOGY

Applications are invited from men and women for the above post to work on a project entitled 'The role of adenosine and cAMP in the regulation of amino acid-mediated neurotransmission in the olfactory cortex'. Applicants should possess or expect to be awarded a good honours degree in Biochemistry, Pharmacology, Physiology, Pharmacy or some other appropriate discipline and will be expected to register for a higher degree. Tenable 3 years from October 1979. Initial salary £3,384 p.a. Applications including a c.v. and names and addresses of two referees to The Registrar and Secretary, The University, Sheffield S10 2TN by May 31. Further information from Dr G. G. S. Collins (0742 78555 Ext. 4659) Quote ref: R 279/G.

616(A)

### UNIVERSITY OF SYDNEY CHAIR OF BIOCHEMISTRY

Applications are invited for a Chair of Biochemistry which will become vacant when Professor K. W. Taylor returns to the United Kingdom at the end of May 1979. The occupant of the McCaughey Chair of Biochemistry is Professor R. G. Wake who has interests in microbial molecular biology. The Boden Chair of Human Nutrition within the Department of Biochemistry is held by Professor A. S. Truswell. The Department of Biochemistry has major teaching responsibilities not only in the Faculty of Science but also in the Faculties of Medicine, Veterinary Science and Dentistry, and an appropriate research interest would be an advantage.

Salary will be at the rate of \$A33,061 per annum, plus a pre-clinical loading of \$A2,500 per annum, if appropriate.

A statement of conditions of Appointment and Information for Candidates may be obtained from the Registrar, University of Sydney, N.S.W. 2006, Australia, with whom applications close on May 31, 1979. Information also available from Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF.

631(A)

### UNIVERSITY OF SIERRA LEONE (Fourah Bay College)

Applications are invited for the post of

#### SENIOR LECTURER/LECTURER

in ORGANIC CHEMISTRY tenable from September 1, 1979. The appointee would be expected to give courses to general and honours degree levels in three or more of the following areas:—The Chemistry of Natural Products, Structural Organic Chemistry, Stereochemistry, Organic Reaction Mechanisms, Classical Organic Chemistry. Salary scales: Senior Lecturer: Le6,243 to Le7,601 per annum. Lecturer: Le4,488 to Le6,897 per annum (£1 sterling equals Le2.20). Family passages; superannuation scheme or contract terms; various allowances; car loan negotiated; part-furnished accommodation at reasonable rent or allowance in lieu. Detailed applications (two copies) with curriculum vitae and naming three referees to the Secretary, University of Sierra Leone, Private Mail Bag, Freetown, Sierra Leone by June 17, 1979. Applicants resident in the U.K. should also send one copy of their application to the Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address.

### PLANT MOLECULAR BIOLOGIST ZOECON CORPORATION

Zoecon Corporation, a leader in innovative agricultural chemical research, is establishing a major research effort in higher plant molecular biology. Research directions will include the application of the techniques of molecular biology to crop improvement. Qualified scientists will join a research team working in a unique scientific environment. Zoecon offers an opportunity to develop and direct a research program, the intellectual stimulation of interaction with excellent colleagues and the opportunity to contribute to the expansion of this exciting field. Individuals with expertise in plant genetics, biochemistry and physiology are encouraged to apply. The positions require a Ph.D. in a field of plant biology, preferably with post doc experience.

Zoecon is a division of Occidental Petroleum Corporation with substantial domestic and international operations. Corporate headquarters and corporate research are located in the Stanford Industrial Park, in close proximity to San Francisco. Submit detailed résumé in confidence to:

Kathy Moore  
Manager, Employee Relations  
Zoecon Corporation  
975 California Avenue  
Palo Alto, California 94304.

## Portsmouth Polytechnic Department of Electrical and Electronic Engineering

# Research in Oscillator Modelling

Applications are invited from suitably qualified Physicists or Engineers to undertake research in the synthesis of radio frequency and microwave oscillators having optimised short term frequency stability and jitter characteristics. The research leading to Ph. D and supported by a Science Research Council Studentship is to be carried out in collaboration with Plessey Radar, Isle of Wight, who will provide supplementary financial support.

Further details may be obtained from Mr. P. Bradsell, Plessey Radar, Newport Road, Cowes, Isle of Wight, tel. Cowes (0983) 294141, or from Dr. E. Vilar, Department of Electrical and Electronic Engineering, Anglesea Road, Portsmouth, tel. Portsmouth (0705) 27681.

# KING FAISAL UNIVERSITY

## College of Veterinary Medicine and Animal Resources

### Hofuf, Saudi Arabia

Faculty positions are presently open for the 1979-1980 academic year in the following fields. Candidates should hold Doctors or Bachelors Veterinary qualifications and have had teaching experience.

GENETICS and BREEDING  
VETERINARY CLINICAL PATHOLOGY/HISTOPATHOLOGY  
BIOLOGY  
VETERINARY GYNAECOLOGY and OBSTETRICS  
CLINICAL PARASITOLOGY  
VETERINARY ANATOMY/HISTOLOGY  
ANIMAL HUSBANDRY

VETERINARY BACTERIOLOGY  
FORENSIC MEDICINE and TOXOLOGY  
FOOD HYGIENE and MEAT INSPECTION  
VETERINARY MEDICINE and THERAPEUTICS  
MARINE RESOURCES and FISH DISEASES  
MATHEMATICS  
VETERINARY SURGERY  
VETERINARIAN

#### Salary Ranges

	Monthly Salary in Saudi Riyals	Approximate Annual Sterling Equivalent
Professor .. .. .	6,595 - 8,995	£11,621 - £15,850
Associate Professor .. .. .	5,835 - 7,585	£10,282 - £13,366
Assistant Professor .. .. .	4,695 - 7,215	£8,273 - £12,713
Lecturer (D) .. .. .	3,385 - 5,785	£5,965 - £10,194
Lecturer (B) .. .. .	2,780 - 4,780	£4,899 - £8,423
Demonstrator (D) .. .. .	2,780 - 4,780	£4,899 - £8,423
Demonstrator (B) .. .. .	2,225 - 3,975	£3,973 - £7,004

Plus Professional Allowance: 20% for Veterinarians; 30% for Physicians

Local transport allowance for 10 months of S.R. 400-600 per month, approximate sterling equivalent of £587-£881 for 10 months.

#### Benefits

There is no Income Tax payable to the Saudi Arabian Government. Free furnished accommodation is provided. Assistance with children's education costs. Return annual air fares for family of four. 60 days paid annual leave. Baggage allowance of 50% of one month's salary payable on taking up post. Contracts for one year, renewable.

Send two copies of curriculum vitae, one copy of certificates, names, addresses and telephone numbers of three references to:

Dr Ibrahim El Desougi Mustafa, Dean, College of Veterinary Medicine, King Faisal University

P.O. Box 2, Sunbury-on-Thames,  
Middlesex TW16 5JP, England

OR c/o Saudi Arabian Educational Mission,

### UMIST

#### UMIST Pollution Group

The members of the UMIST Pollution Group are responsible to the Assistant Director of the jointly organised UMIST/University of Manchester Pollution Research Unit, which consists of a multi-disciplinary group of staff whose interests cover the Technical, Legal, Economic and Social aspects of pollution. The one-year M.Sc. Course in Pollution and Environmental Control has been accepted by the S.R.C. as suitable for the tenure of its Advanced Course Studentships. Applications are invited for the following posts based at UMIST.

#### Lecturer (Reference UPG/68/AD)

The Scientific, Technical and Engineering activities of the UMIST Group are undergoing expansion, and a lecturer is now required. The successful applicant will be expected to make significant contributions to the M.Sc. Course as well as to undergraduate courses in other departments, and to pursue his/her own research interests, both within the Group as well as in collaboration with other departments. Applicants will be considered primarily on the basis of their personal achievements rather than on their conformity to a prescription of suitable interests, but those offering expertise in the fields of Public Health Engineering or Noise Pollution and its Control may well offer the most effective means of complementing the existing staff interests.

Salary will be on the scale £3,883 to £7,754 per annum (subject to revision from October 1978).

#### Project Officer (Reference UPG/69/AD)

In addition to the normal academic pursuits the unit operates a service to industry in topics falling within the pollution and environmental control field and a vacancy now exists for a full time Project Officer to be responsible to the Assistant Director for the day-to-day operation of this service. Versatility and competence in the practical skills necessary to the performance of this service as well as enthusiasm in consolidating opportunities to create new work will be important qualities in the successful candidate. Some involvement in longer term projects will be encouraged in order to enable the Project Officer to maintain his acquaintance with technical developments.

Salary will be on the scale £3,883 to £6,555 or £6,317 to £7,754 per annum subject to qualifications and experience (subject to revision from October 1978).

Application Form and Conditions of Appointment may be obtained from the Registrar, UMIST, P.O. Box 88, Manchester M60 1QD. Appropriate reference should be quoted. Informal enquiries should be addressed to Dr R. F. Griffiths. 640(A)

### UNIVERSITY OF LONDON INSTITUTE OF OBSTETRICS AND GYNAECOLOGY Hammersmith Hospital

A vacancy exists in the Research Laboratories of the Institute of Obstetrics and Gynaecology, Hammersmith Hospital, for a graduate biochemist, preferably with previous experience in prostaglandin work or tissue culture. This is a three-year project to investigate the role of prostacyclin in fetal growth retardation and will lead to an M.Phil./Ph.D. degree. There will be some collaboration with the Department of Clinical Pharmacology, Royal Postgraduate Medical School. The starting date would be June/July 1979. Please send one copy of curriculum vitae to Professor M. G. Elder, Institute of Obstetrics and Gynaecology, Hammersmith Hospital, Du Cane Road, London W12 0HS by Friday May 18. 645(A)

### THE MIDDLESEX HOSPITAL MEDICAL SCHOOL (University of London) POSTDOCTORAL RESEARCH ASSOCIATE

Applications are invited for a three-year appointment supported by the Science Research Council, to work on adhesion and locomotion of tissue cells. Candidates should possess a Ph.D. degree, or expect to obtain one this year. Salary £4,857 per annum, rising to £5,340 per annum (inc. London Allowance). Applications, including curriculum vitae and the names of two referees to Dr David Gingell, Department of Biology as Applied to Medicine, The Middlesex Hospital Medical School, London W1P 6DB. 646(A)

### THE UNIVERSITY OF HULL DEPARTMENT OF BIOCHEMISTRY BIOLOGICAL CHEMIST/ BIOCHEMIST

Applications are invited for a **Post-doctoral Research Assistant** for an attractive and interesting research project concerning the structure and function of iron-binding compounds of the mycobacteria. The position which is created by a grant from the SRC also provides for technical assistance. Candidates should have or expect to have obtained their Ph.D. before the starting date.

Salary will be on the lower part of the scale £3,883 to £4,882 (under review).

### BIOCHEMIST/ MICROBIOLOGIST

Applications are also invited for a graduate **Research Assistantship** for a related project involving mycobacteria of medical and clinical importance. The position is created by a grant from the MRC and will involve some co-operation with the National Institute for Medical Research. Candidates should have or expect to obtain a good honours degree in an appropriate subject.

Salary will be on the scale £3,384 to £3,883 (under review).

Both positions are to start October 1, 1979 and are for three years (subject to satisfactory progress); they will be under the direction of Dr Colin Ratledge.

Applications should give full details of education, qualifications and research experience, where appropriate, together with the names of two referees and should be sent by May 28, 1979 to Dr C. Ratledge, Department of Biochemistry, The University of Hull, Hull, HU6 7RX from whom further details of both positions may be obtained. 601(A)

## Centre for Applied Microbiology & Research, Porton Down, Therapeutic Products Laboratory

The Therapeutic Products Laboratory at the new Centre is concerned with the research, development and production of microbial enzymes and human proteins for clinical use. The Laboratory already manufactures Asparaginase that is widely used for the treatment of leukaemia and has other enzymes in various stages of development. The manufacture of human growth hormone will begin shortly and a capability is being developed for the large-scale freeze-drying of therapeutic products in vials. The Posts described below are likely to suit the person who wants to play a well-defined and worthwhile role in a team that has the common purpose of producing new therapeutic products for clinical use.

### Microbial Screening Section

## Senior Grade Microbiologist

The scientist appointed will be head of this section and responsible for:

- (i) Research, development and application of screening and selective procedures to find new (natural or genetically contrived) microbial sources for therapeutic enzymes.
- (ii) Production of cell paste from promising strains for enzyme purification, characterisation and biological evaluation.
- (iii) Supervision of quality control tests for microbial contamination.

**Qualifications:** Honours degree in Microbiology or Biochemistry and a wide experience in microbiological research. Experience in fermentation technology would be an advantage.

### Process Development Section

## Biochemist or Chemist

The successful candidate will be appointed as a Basic Grade Microbiologist and will be responsible for:

- (i) Development of processes for the purification of microbial enzymes and other proteins to the requirements of the Medicines Act.
- (ii) Research into many problems related to the manufacture of pharmaceutical products.
- (iii) Characterisation of enzymes with respect to substrate specificity and stability after storage and freeze-drying.

**Qualifications:** Honours degree in Biochemistry/Chemistry and preferably at least three years experience in protein fractionation and enzymology.

### Protein Chemistry Section

## Biochemist or Pharmacologist

The successful candidate will be appointed as a Basic Grade Microbiologist and will be responsible for the following research programme.

- (i) Investigation into the effects of chemical modification on the biochemical and biological properties of proteins with a view to improving the efficacy of therapeutic products in man.
- (ii) Design and operation of a wide variety of animal tests for the evaluation of therapeutic products.

**Qualifications:** Honours degree in Biochemistry/Pharmacology and preferably at least three years postgraduate research experience.

### Therapeutic Enzymes Section

## Biochemist or Chemist

The successful candidate will be appointed as a Senior Medical Laboratory Scientific Officer and will be responsible for:

- (i) Large-scale purification of Asparaginase and other microbial products from cell extracts.
- (ii) Development and performance of quality control tests to comply with the requirement of the Medicines Act.

**Qualifications:** University degree or HNC in Biochemistry or Applied Biology or Chemistry and experience in protein chemistry and separation techniques.

If any candidate should require further details of the above posts they should contact Dr J. E. Benbough, Deputy Director, Therapeutic Products Laboratory (Idmiston 610391) and he will be pleased to arrange visits to C.A.M.R. by candidates.

Applications to Mr Paul Murphy, Centre for Applied Microbiology and Research, Porton Down, Salisbury, Wiltshire SP4 0JG.

N.H.S. terms and conditions of service will apply to all these posts.

### Analytical Chemistry Section

## Two posts for Chemists or Biochemists

The Senior post will be filled as a Senior Medical Laboratory Scientific Officer. The successful candidate will be responsible for:

- (i) Organising and conducting analysis of amino acids, trace metals, enzymes and a wide variety of other substances.
- (ii) Compiling documents relating to the quality control of materials used for the manufacture of therapeutic products.
- (iii) Developing rapid methods for assay of enzymes and hormones.

**Qualifications:** University degree in Chemistry or Biochemistry or F.I.M.L.S. and several years experience in analytical work.

The second post in this section will be filled as a Medical Laboratory Scientific Officer. The successful candidate will be responsible for the operation of a wide variety of analyses in biological samples.

**Qualifications:** HNC (or equivalent) and preferably some experience in biochemical or clinical analysis.

### Central Services Section

## Senior Medical Laboratory Scientific Officer

The successful candidate will be responsible for:

- (i) Organisation of services for the Therapeutic Products Laboratory.
- (ii) Preparation of sterile areas for aseptic operations.
- (iii) Organisation and operation of sterile-filtration of bulk therapeutic products.
- (iv) Organisation of quality control tests on finished clinical products and the packaging of vials for distribution.
- (v) Management and training of Ancillary workers.

**Qualifications:** F.I.M.L.T. or the equivalent and experience in medical (or pharmaceutical) laboratory practices. We are looking for someone who is sufficiently versatile and well-organised to execute a wide range of operations used in pharmaceutical manufacture.

### Human Proteins Section

## Medical Laboratory Scientific Officer

The successful candidate will provide technical assistance for:

- (i) Purification of Human Growth Hormone for clinical use.
- (ii) Research and development work on other human proteins.
- (iii) Quality control tests involving protein separation techniques and immuno-assays.

**Qualifications:** HNC (or equivalent) in Applied Biology or Biochemistry or Chemistry.

### Freeze-Drying Section

## Medical Laboratory Scientific Officer

The successful candidate will provide technical assistance for:

- (i) Small- and large-scale freeze-drying of pharmaceutical products such as enzymes and vaccines.
- (ii) Operation and maintenance of freeze-dryers and related scientific instruments.
- (iii) Experimental freeze-drying of new products involving biophysical characterisation.

**Qualifications:** University degree or HNC (or equivalent) in Chemistry, Physics or Applied Biology. Some mechanical aptitude would be an advantage.

### Salary Scales:

Senior Grade Microbiologist .....	£5,451	to	£6,837
Basic Grade Microbiologist (with honours degree 1st or 2nd class) .....	£3,486	to	£4,899
Senior Medical Laboratory Scientific Officer .....	£4,347	to	£5,769
Medical Laboratory Scientific Officer .....	£3,261	to	£4,680

Closing date for applications: May 25, 1979

## FACULTY OPENINGS exist at the Higher Institute of Technology (Brack) Socialist Peoples Libyan Arab Jamahiriya

in:

### ENVIRONMENTAL TECHNOLOGY DEPARTMENT

**Applied Statistician/Biometrician:** M.Sc., Ph.D., to teach basic statistics applied to biology, ecology and medicine.

**Analytical Chemist:** M.S., Ph.D., Teaching and practical experience in general analytical and instrumental methods, or experience in water or environmental analysis.

**Environmentalist:** M.S., Ph.D., In environmental studies and geographical aspects. Teaching and practical experience required.

**Ecologist:** M.S., Ph.D., Experience in warm climates preferred. Interest in field work is essential.

**Environmental Engineer:** M.Sc., Ph.D., or Engineering Degree. To teach environmental engineering relevant to a developing country. Teaching and practical experience in "warm" climates is an advantage.

### Technologists, Technicians/Demonstrators:

1. With degree or extensive experience in preparing and teaching ecology laboratory practicals. Knowledge of electronics is helpful.
2. Experience in analytical chemistry and instrumental methods of analysis. Environmental Microbiologist with Water, Soil and Air analysis experience.

### Medical Technology Department

**Hematologist - Serologist:** M.S., Ph.D. or Certified Medical Technologist. To teach Hematology and Serology. Teaching and practical experience desired.

**Demonstrators, Technologists, Technicians:** For teaching laboratory in Biochemistry, Clinical Chemistry, Hematology and Medical Microbiology.

### Food Technology Department Lecturers

**Food Analytical Chemist:** M.Sc., or Ph.D. with teaching and practical works experience.

**Food Nutritionist:** B.Sc., or M.Sc., with teaching and laboratory experience.

**Technologist/Demonstrator and 2 Technicians:** B.Sc./HND or equivalent qualifications for laboratory demonstration.

All applicants must be fluent in spoken English, the language of instruction. Appointments depend on qualifications of appointees. No age limit exists on applicants. Fringe benefits include free air conditioned housing, medical services, transportation and terminal gratuity.

Applications should be addressed to:

**The Dean  
Higher Institute of Technology  
Lyster Campus, Hal-Far, Malta.** W94(A)

Centre for Applied Microbiology & Research  
Porton Down  
Special Pathogens Reference Library

## Top Grade Microbiologist

Applications are invited from Scientists/Microbiologists with an appropriate higher qualification for this post. The laboratory is concerned with the diagnosis of severe human microbial infections, particularly those caused by viruses such as Lassa, Marburg and Ebola. It is also actively concerned with research on such viruses and the diseases they cause. Experience in the handling of dangerous pathogens and of work in high containment laboratories will be an advantage.

Salary on NHS Top Grade Biochemist/Physicist scale (£8,877 to £10,347). Other terms and conditions of service generally as for appointments in the NHS.

The laboratory may be visited by arrangement with the Director, Dr D. I. H. Simpson. Telephone 0980-610391.

Full details of this post may be obtained from Mrs M. Bushby, Centre for Applied Microbiology & Research, Porton Down, Salisbury, Wilts SP4 0JG, to whom applications together with curriculum vitae, stating date of birth, qualifications, experience and published work, and naming 3 referees should be sent to arrive not later than May 18, 1979. 602(A)

PH  
LS

Public Health Laboratory  
Service Board.

### AUSTRALIAN NATIONAL UNIVERSITY

John Curtin School of  
Medical Research  
DEPARTMENT OF  
PHARMACOLOGY  
RESEARCH FELLOW

Applications are invited for appointment to the above-mentioned post. The successful applicant will be expected to pursue research under the general direction of Professor D. R. Curtis into synaptic mechanisms within the mammalian central nervous system at a cellular level, and to be familiar with the relevant anatomical, biophysical, and pharmacological techniques. Further information may be obtained from Professor Curtis, in the University.

Appointment will be for two years in the first instance with the possibility of extension to a maximum of five years.

**CLOSING DATE: JUNE 15, 1979.** Salary on appointment will be according to qualifications and experience within the range: \$A15,786 to \$A20,606 per annum. Present exchange rates are \$A1 : 56p.

Reasonable appointment expenses are paid.

Superannuation benefits are available for applicants who are eligible to contribute. Assistance with finding accommodation is provided for an appointee from outside Canberra.

The University reserves the right not to make an appointment or to make an appointment by invitation at any time.

Prospective applicants should obtain the further particulars from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. 630(A)

### UNIVERSITIES OF MANCHESTER AND LIVERPOOL

Universities Research Reactor  
Risley, near Warrington

### EXPERIMENTAL OFFICER (Assistant Analyst) IN THE ACTIVATION ANALYSIS SERVICE

Applications are invited for the post of EXPERIMENTAL OFFICER (ASSISTANT ANALYST) in the Activation Analysis Service of the Universities Research Reactor. The successful candidate will be expected to plan and carry out trace element analysis of a wide range of materials submitted to the Service by Industrial and University research workers. The techniques usually involved are those of thermal neutron activation; other radiochemical techniques are used when necessary. Facilities available include the 300kW nuclear reactor on the site, a fully equipped Radiochemical Laboratory, comprehensive detection and nucleonic equipment. Candidates should have a sound knowledge of inorganic chemistry; experience in inorganic analysis or radiochemistry would be an advantage, together with at least pass degree or equivalent in chemistry. Salary range: £3,384 to £5,604 per annum (under review) U.S.S. Particulars and application forms (returnable by May 25) from the Registrar, The University, Manchester M13 9PL Quote ref: 92/79/N.

666(A)

## Administrative Appointments for Scientists

Science graduates interested in a career in research administration—giving opportunities to be involved with the latest developments in medicine and biology—are invited to apply for appointment as a Scientific Administrative Officer in the Council's London office. The Council has an annual budget of some £60m and is the main government agency for promoting medical research.

The successful candidate is likely to be aged between 30–40, with some experience both of biomedical research at a post-doctoral level and of administration, and with broadly informed interest in science and medicine. The job carries key responsibility for day-to-day liaison between the Council and research workers, both in the Council's own research establishments and in Universities, Medical Schools, Hospitals and Research Institutes.

The Council's headquarters staff are appointed on terms and conditions analogous to those of the Civil Service. Subject to satisfactory completion of a 2 year probationary period, the appointment will be permanent. The salary scale (Principle Scientific Officer grade) offered is £6,609 to £8,461 (currently under review) plus £524 London Weighting with superannuation provision; and there is opportunity for promotion.

Further information and application forms may be obtained by writing or telephoning to Miss Margaret Gale, Medical Research Council, 20, Park Crescent, London W1N 4AL (01-636 5422 Ext. 35); the closing date for applications is May 14, 1979.

# MRC

Medical Research Council

680(A)

### UNIVERSITY OF THE WEST INDIES—TRINIDAD

Applications are invited for the following posts:—

**LECTURER/ASSISTANT LECTURER BIOCHEMISTRY**  
DEPARTMENT OF BIOLOGICAL SCIENCES with interest and training in Nutrition, Chemical Microbiology, Plant Biochemistry or Natural Products.

**LECTURER/ASSISTANT LECTURER SOIL PHYSICS**  
DEPARTMENT OF SOIL SCIENCES with experience and interest in applied aspects of soil water relations, tillage, drainage, irrigation and land reclamation.

**RESEARCH FELLOW/JUNIOR RESEARCH FELLOW** (two posts)  
DEPARTMENT OF SOIL SCIENCES with postgraduate qualification in Soil Physics or Agricultural Engineering and interest in management of clay soils for production of annual food crops. Appointee may be stationed in Guyana.

Salary scales (1977/8 under review)  
Lecturer/Research Fellow—TT\$19,071 to TT\$29,799 per annum. Assistant Lecturer/Junior Research Fellow—TT\$15,480 to TT\$16,974 per annum (£1 sterling equals TT\$5.02). F.S.S.U. Unfurnished accommodation if available at 10 per cent or furnished at 12½ per cent or housing allowance of 20 per cent or pensionable salary. Family passages. Study and Travel Grant. Detailed applications (two copies) with curriculum vitae and naming three referees to Secretary, U.W.I., St Augustine, Trinidad, as soon as possible. Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.

607(A)

### UNIVERSITY OF HONG KONG

**LECTURESHIP/ ASSISTANT LECTURESHIP IN BIOCHEMISTRY**

Applications are invited for the post of Lecturer/Assistant Lecturer in Biochemistry. Applicants from any field of research endeavour will be considered; experience in immunochemistry or in teaching dental students will be an advantage, but is not essential.

Annual salaries (superannuable) are: Lecturer HK\$63,540 by 4,260 to 72,060; Assistant Lecturer HK\$46,260 by 4,320 to 59,220. (£1 = HK\$10.70 approx). A medically-qualified appointee who has completed his pre-registration year will be appointed as a Lecturer at the minimum point of the scale. Starting salary will depend on qualifications and experience.

At current rates, salaries tax will not exceed 15% of gross income. Housing at a rental of 7½% of salary, education allowances, long leave and medical benefits are provided.

Further particulars and application forms may be obtained from the Association of Commonwealth Universities (Apps), 36 Gordon Square, London WC1H 0PF, or the Assistant Secretary (Recruitment), University of Hong Kong, Hong Kong.

Closing date for applications is June 30, 1979.

672(A)

## UNIVERSITY OF MAINE

With the establishment of the Center for Marine Studies, the University of Maine is placing priority emphasis on the development of a strong, competitive research and graduate education program in marine resources. Nominations and applications are invited for the following positions.

### CHAIRPERSON DEPARTMENT OF OCEANOGRAPHY

The Oceanography Department, a graduate department offering M.S. and Ph.D. degrees, is primarily housed at the University's marine laboratory at Walpole Maine. It currently has a faculty of 8. Present research activities include ecology of sub-boreal estuarine organisms, environmental biology and geochemistry, aquaculture and geological oceanography.

#### Responsibilities:

to serve as chief administrative officer, and develop a coordinated research program in physio-chemical estuarine processes.

#### Qualifications:

- (1) innovative leadership and administrative capability,
- (2) continuing scholarly achievements,
- (3) evidence of consistent success in funded research,
- (4) earned doctorate.

Academic appointment as Associate or Professor, tenure track. Salary open within University constraints.

### FISHERIES POPULATION DYNAMACIST DEPARTMENT OF ZOOLOGY

The Zoology Department, with a current faculty of 18, is primarily housed on the Orono campus, and includes the Cooperative Fisheries Unit. Ten of the faculty have research interests in marine or freshwater biology.

#### Responsibilities:

to develop a graduate education and research program on population dynamics of fishes.

#### Qualifications:

- (1) earned doctorate,
- (2) additional professional experience in marine fisheries biology desirable.

Academic appointment as Assistant Professor, initially one year with probability of additional 2-4 year University commitment.

### MIGRATORY FISH BIOLOGIST MIGRATORY FISH RESEARCH INSTITUTE

The Migratory Fish Research Institute is an interdisciplinary group of primarily Zoology faculty whose research interests focus on the biology of migratory fishes.

#### Responsibilities:

to collaborate in research on oceanic and estuarine migrations of larval and juvenile eels, and to assist in research proposal development.

#### Qualifications:

- (1) earned doctorate,
- (2) training and experience in fish migration and orientation preferred, and,
- (3) marine background or orientation.

Research appointment, initially one year with probability of second year continuation and possibility of third year depending on extramural program funding.

### MARINE STATION ADMINISTRATIVE OFFICER

The Ira C. Darling Center is the marine laboratory of the University of Maine. It is located on a 152 acre site on the Damariscotta estuary and includes Lowe's Cove. The facility comprises 10,000 square feet of laboratory and teaching space, including an Aquaculture Center, a developing conference center, a library, dockside facilities, and a fleet of small vessels.

#### Responsibilities:

to serve as the Chief Administration officer of a semi-isolated marine facility in support of educational and research programs, to be responsible for budget development and control, and for an expanding promotional/developmental activity.

#### Qualifications:

- (1) extensive administrative experience,
- (2) evidence of ability to communicate effectively with the public, and,
- (3) experience in sea-oriented organisation including logistics, desirable.

Salary \$16,000 to \$18,000.

Applicants should send complete resumes, samples of publications, and names of three referees, by May 15, 1979, to:

Secretary, Search Committees  
Center for Marine Studies  
Room 14, Coburn Hall  
University of Maine at Orono  
Orono, ME 04469 U.S.A.

The University of Maine is an Equal Opportunity/Affirmative Action Employer.

W95(A)

# Opportunities in Pharmacological Research

The Pharmaceutical Division of Reckitt and Colman—a rapidly growing research-based unit requires scientists to consolidate and further expand its already successful biological research teams.

Our analgesic, immuno-inflammatory and CNS research teams have already achieved considerable success and have been associated with several recent therapeutic successes (e.g. buprenorphine, etorphine, diprenorphine, fenclofenac and sodium valproate). To continue and extend these successes we intend to expand our biological research teams in all of these projects. In addition, the increasing demands by drug regulatory authorities around the world has also necessitated the enlargement of the pharmacological development teams concerned with the acute safety and endocrinological effects of prospective drugs.

Such expansion will present several types of opportunities to prospective candidates:- to post-doctoral scientists with specialist experience either in academia or industry and leadership ability and also to newer graduates with a minimum of good honours degree and a sound knowledge of pharmacological principles.

The importance Reckitt and Colman continue to attach to pharmaceutical research will be reflected in the salaries offered with these appointments. Contributory pension and bonus schemes are in operation. For an application form or for further information concerning these appointments please write in complete confidence to:

Miss N. V. McGeown, Personnel Officer,  
Reckitt and Colman Pharmaceutical Division,  
Dansom Lane, Hull HU8 7DS.

# ETH Zürich

The Swiss Federal Institute of Technology in Zürich has an opening for the

## Chair of Applied Microbiology

The new professor is responsible for teaching and research in biotechnology, especially in its application to biologically mediated processes in natural aquatic systems and continuous fermentations with mixed microbial biocenoses such as in water and waste treatment plants. It is desirable that the applicant be ready to act as a head of the department of biology of the Federal Institute for Water Resources and Water Pollution Control associated with the Swiss Federal Institute of Technology.

The successful applicant should have several years of relevant experience and proven ability to perform and direct research. He will be expected to teach, at both undergraduate and graduate levels, and to cooperate with various research groups.

Applications, with curriculum vitae and list of publications, should be sent by May 31, 1979, to Prof. H. Ursprung, President, Swiss Federal Institute of Technology, CH-8092 Zurich.

W87(A)

UNIVERSITY OF FRIBOURG  
Switzerland

Applications are invited for the post of

### PROFESSOR OF ORGANIC CHEMISTRY

eventually serving as well as head of department of organic chemistry. The department has three full professors and around 20 graduate students. Teaching languages are French and German. Salary is according to government scale.

Applications with detailed curriculum, a complete list of publications and copies of the most important publications are to be sent before June 15, 1979 to F. P. Emmenegger, dean of the Faculty of Science, University of Fribourg, Pérolles, CH-1700 FRIBOURG, Switzerland.

W97(A)

### PROFESSORSHIP IN MOLECULAR GENETICS

Seeking individual for Professorship in Molecular Genetics. Individual must be established investigator for research and teaching in molecular genetics.

Position in Cancer Centre with broad laboratory research programs including cellular genetics and development, tumor immunology, viral oncology, and chemical carcinogenesis.

Salary negotiable dependent on level of experience and academic rank of applicant. Send curriculum vitae and inquiries to: Chairman, Molecular Genetics Professor Search Committee, Cancer Center/Institute of Cancer Research, Columbia University, 701 West 168th Street, New York, New York 10032.

An Equal Opportunity Employer.

UNIVERSITY OF OTAGO  
Dunedin, New Zealand  
WOLFF HARRIS CHAIR  
OF PHYSIOLOGY

The University Council invites applications from medical or science graduates for appointment to the Wolff Harris Chair of Physiology, at present occupied by Professor J. R. Robinson who is retiring at the end of the year.

Professorial salaries which are regularly reviewed, are paid within the following ranges:—

Medical NZ\$30,365 to NZ\$33,865 per annum.

Science NZ\$23,865 to NZ\$29,865 per annum.

(Both rates inclusive of NZ\$365 per annum cost-of-living allowance).

Further particulars are available from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close on June 30, 1979

## British Museum (Natural History) London

## Entomologists

The British Museum (Natural History) is an institution for taxonomic research and an educational focal point for the public. The main aim of the research is to produce definitive accounts of the world's animals, plants and minerals as well as the presentation of an extensive collection of fossils. These posts are in the Department of Entomology which contains the largest and most comprehensive collection of insects in the world and offers successful candidates unrivalled research opportunities and facilities.

**Medical Insect Studies**

The successful candidate will supervise and participate in taxonomic research on one or more families of medically important Diptera and become a specialist adviser on mosquitoes. The work will also involve improving and maintaining the national collection of medical insects.

Candidates, normally aged under 32, should have a good honours degree or equivalent in zoology, preferably with entomology. At least 2 years' relevant postgraduate experience is essential.

Appointment as Senior Scientific Officer (£5,675 to £7,420) or Higher Scientific Officer (£4,620 to £5,970) according to qualifications and experience. **Salaries under review.** Promotion prospects. Non-contributory pension scheme.

**Taxonomic Research on Coccoidea**

The successful candidate will participate in taxonomic research studies on scale insects and mealy bugs, and maintain and improve the Department's collection through exchanges with other specialists and by collecting and rearing. The work will involve a great deal of microscope slide preparation, and some supervision of junior staff. In addition, the entomologist will deal with enquiries from other institutions and members of the public.

Candidates, normally aged under 30, should have a good honours degree or equivalent in zoology, preferably with entomology. Relevant postgraduate experience is advantageous; at least 2 years is essential for Higher Scientific Officer level.

Appointment as Higher Scientific Officer (£4,620 to £5,970) or Scientific Officer (£3,360 to £4,940) with starting salary according to qualifications and experience. **Salaries under review.** Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by May 31, 1979) write to Civil Service Commission, Alencon Link, Basingtoke, Hants RG21 1JB, or telephone Basingtoke (0256) 68551 (answering service operates outside office hours). **Please quote ref: SB/54/DK.**

OrganizationDEVELOPMENTAL  
BOTANY GROUP

## SCIENTIFIC OFFICER

Applications are invited for a Scientific Officer to assist in a research team led by Dr Daphne J. Osborne, which is engaged in physiological, biochemical and ultrastructural studies relating to crop-weed associations.

These include cellular events in seed dormancy, viability and germination, effects of stress, control of meristem growth and shedding of plant parts.

The duties of the post will be mainly concerned with electron microscopy.

Candidates should possess an honours degree, H.N.C. or equivalent in a biological subject with relevant post qualifying experience.

Appointment as Scientific Officer in a scale rising from £2,839 to £4,415 by 12 annual increments. Starting salary will depend on qualifications and experience.

Further particulars and application forms from the Secretary, A.R.C. Weed Research Organization, Begbroke Hill, Yarnton, Oxford OX5 1PF, quoting Ref. 13/79. Closing date May 18, 1979. 643(A)

THE UNIVERSITY  
OF LEEDSDepartment of Inorganic  
and Structural  
Chemistry

Applications are invited for a temporary post of POST-DOCTORAL RESEARCH FELLOW in the above Department from inorganic or biochemists. Candidates should already possess, or expect to receive within the next few months, a Ph.D. degree. Experience in mechanistic studies would be valuable. The appointee will take part in a project, supported by S.R.C., on electron transfer reactions of blue copper proteins, iron-sulphur proteins and cytochrome c. The appointment will be for a fixed period of either one or two years commencing October 1, 1979.

Starting salary in the range £3,883 to £4,382 on the IA scale for Research and Analogous Staff (£3,883 to £6,555) (under review), according to age, qualifications and experience.

Informal enquiries may be addressed in the first instance to Dr A. G. Sykes, Department of Inorganic and Structural Chemistry (Tel: 0532-31751, ext. 6068).

Applications (quoting reference number 44/6/D) should be made as soon as possible to the Registrar, The University, Leeds LS2 9JT (from whom further particulars may be obtained). 641(A)

## RESEARCH ASSISTANT

to assist in a project concerned with the identification and mechanism of beta-receptors in myocardial tissue. The project is suitable for a Ph.D. thesis and registration for this higher degree will be encouraged. Applicants should have a degree in Biochemistry (first or upper second class). Those graduating in 1979 may also apply. The post is offered for a maximum of three years. Starting salary £3,615 p.a. Application forms available on request from the House Secretary, Cardiothoracic Institute, 2 Beaumont Street, London W.1 (telephone 01-486 3043). Closing date June 1, 1979.

(This is a readvertisement and previous applicants should not re-apply.) 665(A)

## CENTRAL ELECTRICITY RESEARCH LABORATORIES

Kelvin Avenue, Leatherhead, Surrey, KT22 7SE

# RESEARCH OFFICER

## BIOLOGY SECTION

The Biology Section at CERL, whose research programme includes studies of the environmental consequences of emissions from power stations, requires a graduate/post-graduate environmental scientist to undertake research on certain aspects of the effects of gaseous and particulate emissions ( $\text{SO}_2$ ,  $\text{NO}_x$ , acid precipitation and trace elements) on terrestrial ecosystems. The deposition, uptake and cycling of these atmospheric species in crops and soils are being studied as part of a programme to assess beneficial and detrimental effects of air pollution on crop yield, physiological and biochemical processes in plants, and leaching processes in soils.

The successful candidate will co-operate with physicists and chemists at CERL in the application of information about dispersion and deposition of emissions from power stations and in the development of techniques for studying effects on crop growth, involving measurements of the flux of emissions to and cycling within crops, and their subsequent metabolic fate. Initially, the successful candidate will be particularly involved in micrometeorological and flux measurements associated with the development of systems for fumigating crops both in growth chambers and in the field.

Candidates should have an interdisciplinary background including a good Honours degree in Biology, Physics or Chemistry and preferably postgraduate experience in environmental science or meteorology.

**According to age, experience and qualifications the appointment will be made within incremental salary ranges rising to £6035 or £7050 plus a payment under a Self-Financing Productivity Scheme ranging between £8 and £17 per month.**

The Laboratories are situated in a pleasant part of Surrey and offer attractive conditions of service, and facilities for the total of 800 Research and Support staff engaged in a broad spectrum of research into the materials, technologies and plant performance problems of the Central Electricity Generating Board.

Application forms are obtainable from the Head of Personnel Development & Services Section, Central Electricity Research Laboratories, at the above address or telephone Leatherhead 74488 Ext 363 quoting reference number **RL/30/N**. Closing date is: **Friday 18 May 1979.**

### DEPARTMENT OF BIOPHYSICS King's College London POSTDOCTORAL RESEARCH ASSISTANT

Postdoctoral position supported by the M.R.C. is available from June 1, 1979, to collaborate with Dr H. J. Gould on the molecular cloning and analysis of human immunoglobulin genes.

Starting date not later than September 1, 1979. Salary £3,883 to £6,555 p.a. plus London weighting.

Applications, with curriculum vitae and names of two referees, should be sent to Dr H. J. Gould, Department of Biophysics, King's College, 26-29 Drury Lane, London WC2B 5RL. 626(A)

# EUROPEAN FIELD TRIALS MANAGER

The Agricultural Products Research and Development Division of Pfizer Central Research at Sandwich, Kent, is expanding its capability to conduct opinion leader and field trials throughout Europe (including U.K.) with animal health and performance enhancing products.

Applications are invited for the new position of European Field Trials Manager whose work will embrace both the planning and personal supervision of such field trial programmes in the broad animal health products area.

His or her work will cover both development projects with new product candidates and market support programmes designed to extend the applications and acceptance of existing Company products.

The technical spheres involved include animal performance enhancement in its several guises and the broad anti-infective range of antibacterials, anthelmintics and ectoparasitides.

The successful candidate will work closely with R and D colleagues in relevant scientific disciplines and departments, particularly at the planning stage, and will personally implement agreed trial programmes in the field. He or she will be based at Sandwich, and will spend some 50 per cent of working time in the field, mostly in Continental Europe.

We are seeking a Veterinarian or other suitably qualified individual in the late 20s to early 40s age range, with drug development field trials experience, fluency in at least two European languages (one of them English) and, preferably, existing appropriate field contacts for trial work on commercial premises and at 'expert' locations.

As well as technical suitability, initiative and enthusiasm, the personal qualities required are those appropriate to effective interaction with a variety of collaborators in Europe both within

and outside the organisation, and the overall reliability and ambassadorship essential to operating in part away from home base.

This post will attract a high salary, reflecting both the breadth of responsibility and geographical scope of the duties. A car will be provided. The Company is situated in rural and coastal Kent with many local recreational amenities. We offer generous conditions of employment including bonus, pension, death benefit and salary continuance schemes, flexible working hours and an excellent Sports and Social Club.

This new appointment is an important one in Pfizer's expanding programme of Agricultural Products Research and Development. If you have the qualifications, qualities and experience necessary to make a significant contribution to our operations, please send a brief curriculum vitae, which will be treated in the strictest confidence, to:

**Pfizer**

**R. G. MULHERN, Director, Research Personnel, Pfizer Central Research, Ramsgate Road, SANDWICH, Kent CT13 9NJ or telephone 03046 3511 extension 241 for an application form.**

603(A)

## BRUNEL UNIVERSITY LECTURESHIPS IN THE SCHOOL OF BIOLOGICAL SCIENCES

1. Applications are invited for a lectureship in the Department of Applied Biology. An interest in teaching and research in the general field of Eukaryote Genetics will be a decided advantage.
1. Applications are invited for a lectureship in the Department of Biochemistry.

The salary for both posts will be on the Lecturer scale £3,883 to £7,754 plus £502 London Allowance.

Write for application form and further details for both posts to the Assistant Secretary (Establishment), Brunel University, Uxbridge, Middlesex UB8 3PH or telephone Uxbridge 37188 extension 49. Closing date: May 18, 1979.

THE UNIVERSITY OF MANCHESTER. Department of Medical Biochemistry. 1. RESEARCH TECHNICIAN (Grade 5) required to work on the biochemistry of connective tissues. This position, financed by the Arthritis and Rheumatism Council, is available to the end of March 1981. Applicants should have H.N.C. or equivalent and at least 8 years experience in biochemistry. Familiarity with tissue culture techniques would be an advantage. Salary scale £3,474 to £4,056 per annum. 2. TECHNICIAN (Grade 4) required for a variety of tasks. Candidates should have an O.N.C. and several years relevant laboratory experience. A knowledge of centrifugation would be an advantage. Salary scale £3,222 to £3,708 per annum. Applications for these posts (please specify which) should include details of age, experience and qualifications and the name and address of two referees and be sent to the Secretary, Department of Medical Biochemistry, University of Manchester Medical School, Manchester M13 9PT. 668(A)

## SCIENTIST

### to work on MOTION SICKNESS

at the Institute of Naval Medicine, Alverstoke, Hants, with support administered by the MEDICAL RESEARCH COUNCIL in a 3 year project. The appointee will be of postdoctoral status preferably with some experience in physiology and/or pharmacology. Medical qualifications and/or experience of working with human subjects advantageous.

Salary according to qualifications, experience and age, in the range; £4,600 to £6,500.

Further particulars from the Assistant Secretary, Royal Naval Personnel Research Committee, Room 407, First Avenue House, 40-48 High Holborn, London WC1V 6HE.

# Synthetic Organic Chemistry

Hoechst – one of the largest pharmaceutical companies in the world, with an active international research and development programme – are expanding their drug discovery programme at their research laboratories at Milton Keynes, Bucks, and are seeking a number of organic chemists to join project teams within the department of synthetic organic chemistry.

Candidates should have a real interest in all aspects of synthetic chemistry and be able to apply their innovative and practical skills to medicinal chemistry and the syntheses of compounds for biological testing. For these challenging new posts applications are invited from:

PhD Chemists with up to two years' post-doctoral experience in synthetic organic chemistry.

Graduates (BSc, GRIC) with up to three years' relevant industrial experience.

People who expect to graduate with a relevant first or higher degree this year.

These appointments carry good salaries, with at least four weeks holiday a year. Benefits include flexible working hours, free private health scheme, subsidised restaurant meals, excellent sports and social facilities. Generous relocation assistance will be provided if applicable.

Please write or telephone for an application form to:  
Mr. A. Forrest, Personnel Department, Hoechst UK Limited,  
Walton Manor, Walton, Milton Keynes, Bucks. Tel: Pineham 5068.

## Hoechst

637(A)

## THE DISTILLERS COMPANY LIMITED RESEARCH CHEMIST

We have a vacancy for an honours graduate in chemistry, aged 24 to 29, with experience in chromatographic methods, preferably as applied in food, beverage or flavour analysis. The successful candidate will be expected to develop methods of analysis for constituents of portable spirits and will have the best facilities to adopt his/her analytical expertise to solving problems which arise in spirit manufacture.

The company runs well equipped laboratories in pleasant surroundings. A non-contributory pension scheme is operated and assistance can be given with removal expenses.

For further information and an application form write, with brief details of career to: Dr R. E. B. Duncan, Manager, The Distillers Company Limited, Glenochil Research Station, MENSTRIE, Clackmannanshire. Tel: Alva (0259) 61481.

678(A)

## UNIVERSITY OF MANCHESTER DEPARTMENT OF PHYSICS RESEARCH ASSISTANT

Applications are invited for the above post, supported by the SRC under an agreement with the Daresbury Laboratory. The successful applicant will be responsible for the commissioning of a large NaI total-energy  $\gamma$ -ray spectrometer and for the construction and testing of gas ionization and gas scintillation detectors to be used in the nuclear physics experimental programme at the Daresbury Nuclear Structure Facility. Candidates should have a good honours degree in physics and should possess the necessary attitude for pursuing a programme of apparatus development. Consideration will be given to candidates graduating this summer. The post is tenable for a period ending in April 1981 at a salary in the range £3,384 to £4,882 p.a. Superannuation. Further information is available from Dr J. C. Lisle, The Schuster Laboratory, The University, Manchester, M13 9PL, to whom applications and the names of two referees should be sent by June 1, 1979/N.

604(A)

## MEDICAL RESEARCH COUNCIL LABORATORY ANIMALS CENTRE RESEARCH OFFICER

The Centre's Accreditation Department manages a national scheme concerned with monitoring the quality of laboratory animals of many species produced by commercial breeders and suppliers. The scheme aims to ensure that adequate standards of housing and husbandry are maintained; it acts as an information exchange on sources of supply; and it provides veterinary advice to the centre.

A vacancy in the Research Officer category exists in the department. The post holder will be expected to travel widely in Great Britain. Applications are invited from persons with a degree or equivalent qualification in a biological science, and at least two years research experience. Salary will be related to age, qualification and experience and is supplemented by £354 London Weighting. Contributory pension scheme.

Applications, together with a copy of curriculum vitae and the names of two professional referees, should be addressed to The Director, MRC Laboratory Animals Centre, Woodmansterne Road, Carshalton, Surrey, SM5 4EF. 562(A)

# MRC

Medical Research Council

## UNIVERSITY OF NAIROBI—KENYA

Applications are invited for the following posts in the DEPARTMENT OF BOTANY:—

### SENIOR LECTURER

Applicants should be qualified in any of the following disciplines of Genetics: Molecular Genetics; Population Genetics and Quantitative Genetics. Candidates should also have Ph.D. in Botany with extensive teaching and research experience evidenced by published works. Appointee will be expected to teach undergraduate and postgraduate courses and develop research programmes in their specialism.

### LECTURERS

Applicants should be highly qualified with commitment to teaching and research in any of the following: i) Plant Physiology and Biochemistry with special interest in plant growth and development; ii) Taxonomy (mainly experimental systematics, chemosystematics and plant geography); iii) Microbiology (with interests in mycology and/or microbial genetics); iv) Marine Botany (marine ecology or marine microbiology). Participation in the undergraduate and postgraduate courses and development of research programmes in their areas of specialisation is expected.

Salary scale: Senior Lecturer K£2,988 to K£3,984 per annum, Lecturer K£2,016 to K£3,312 per annum (K£1 equals £1.29 sterling). The British Government may supplement salaries in range £4,278 to £5,430 per annum (sterling) for married appointees and £2,730 to £3,648 per annum (sterling) for single appointees (reviewed annually and normally free from tax) and provide children's education allowances and holiday visit passages. Family passages; superannuation scheme; medical aid scheme; various allowances. Detailed application (two copies) with curriculum vitae and naming three referees to be sent direct to Registrar, University of Nairobi, PO Box 30197, Nairobi, Kenya by May 12, 1979. Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address.

608(A)

## UNIVERSITY OF EDINBURGH

### DEPARTMENT OF FORESTRY AND NATURAL RESOURCES

Applications are invited for two  
lecturer positions in

- (i) **FOREST  
MANAGEMENT**
- (ii) **WILDLIFE  
ECOLOGY**

For position (i) applicants should have a University degree in Forestry and some practical experience of Forest Management. Additional experience in a cognate field, such as mensuration, statistics, economics, resource appraisal or wildlife management would be an advantage.

For position (ii) applicants should be ecologists with some practical knowledge of population dynamics and of the physiology of vertebrates. Additional experience in wildlife management would be an advantage.

The successful candidates will become members of a Department covering a wide range of topics in Ecological Science and the management of renewable natural resources and will be expected to cooperate in teaching in integrated ecology courses as well as in the above areas; they will also be expected to pursue, in collaboration with their colleagues, research on relevant topics.

It is hoped that the successful candidates will take up the positions on October 1, 1979. Salary scale: £3,883 to £7,754 per annum (under review).

Applications (three copies) together with the names of two referees should be lodged not later than June 1, 1979 with the Secretary to the University, Old College, South Bridge, Edinburgh EH8 9YL, from whom further particulars may be obtained. Please quote reference 1041. 600(A)

## UNIVERSITY OF CALIFORNIA, BERKELEY

### College of Natural Resources

Faculty and Agricultural Experiment  
Station Position in the Division of  
Biological Control and Department  
of Entomological Sciences

A position as Professor of Entomology and Entomologist in the Experiment Station will be available July 1, 1979. Qualifications must include a Ph.D. degree with specialisation in the biology, ecology, and systematics of parasitoids and predators of arthropod pests, together with extensive kills and 15 years of experience in these areas, and in foreign exploration, importation, colonisation and evaluation of such agents in biological control programs. Research responsibilities (80%) in the Division of Biological Control will include studies in the biology, ecology and behaviour, and on origin exploration, importation, evaluation, augmentation, and conservation of natural enemies of arthropod pests of agricultural crops and urban plantings, and in the cooperative development of integrated pest management programs. Teaching responsibilities (20%) will be in the Department of Entomological Sciences in the area of biological control. Applicants should send full curriculum vitae, relevant publications and manuscripts (official academic transcripts), and the names of three persons as reference by June 1, 1979 to:

L. E. Caltagirone, Chairman  
Division of Biological Control  
University of California  
Albany, California 94706

The University of California is an equal opportunity, affirmative action employer. W85(A)

The Daresbury Laboratory has a vacancy in the Computational Science group for a scientist with experience in

# COMPUTATIONAL ATOMIC AND MOLECULAR COLLISIONS

The position is at Senior Scientific Officer level.

The successful applicant will be responsible for providing general support for collaborative computational projects involving atomic and molecular collisions being conducted in collaboration with the Universities. The work will include the development and maintenance of large computer programs in this area of science. Applicants should possess a Ph.D. in Physics or Chemistry and have relevant postdoctoral experience in computational atomic and molecular collisions.

The computational science group is part of the Division of Theory and Computational Science. The Division has broad-ranging interests in theoretical and computational physics, chemistry and biological sciences. The Laboratory has a purpose built X-ray and U.V. source and a 30 MV tandem Van de Graff accelerator under construction. It also has powerful computing facilities including an IBM 370/165 on site and a link to two IBM 360/195 computers at SRC Rutherford Laboratory.

Appointments will be made at salaries between £5154 and £6898 depending on age, ability and experience and may be taken up on secondment from a University for a period of five years or on a permanent basis.

Closing date: 17 May 1979.

For further information please write or telephone to the head of the computational science group, Dr. V. R. Saunders (Tel: (0925) 65000 Ext. 204). Applications should be sent together with curriculum vitae and the addresses of two referees quoting reference number DL/672/T to:

The Personnel Officer

## DARESBURY LABORATORY

A post of

### RESEARCH ASSISTANT

for studies leading to a higher degree has fallen vacant in the Department of Geology. Candidates who might wish to carry out research in one of the following projects should apply in writing giving full curriculum vitae and the names and addresses of two referees to the Staff Records Officer, City of London Polytechnic, 117 Houndsditch, London EC3A 7BU quoting reference number 79/34.

(a) Geology of the nappe region of North-east Jotunheim, Norway.

(b) Volcanology of the Tayvallich Lavas and associated Igneous rocks of S. W. Argyll.

(c) The geological evolution of the Pre-cambrian Stora Le Marstrand Series of Northern Orust, Sweden.

The salary scale for Research Assistants is £2,613 to £2,700 to £2,787 plus London Allowance of £474 per annum. 660(A)

## Northern Ireland Forensic Science Laboratory

### Scientific Staff

Applications are invited for the following pensionable posts in the Northern Ireland Forensic Science Laboratory, Newtownbreda Road, Belfast.

The successful candidates will join a team of scientists engaged in the scientific investigations of crime throughout Northern Ireland. The work is interesting and varied and offers wide scope for developing interests in the varied aspects of forensic science.

#### Scientific Officers

**£2,839 – £4,415 (Ref: SB 189/79/N)**

Applicants must be under 27 years of age at December 31, 1979 and possess

- (a) an Honours degree in pure or analytical chemistry; or
- (b) an equivalent qualification acceptable to the Civil Service Commissioners.

Applicants who hope to obtain the requisite qualification in 1979 may apply.

#### Metallurgist

**(Higher Scientific Officer)**

**£4,101 – £5,448 (Ref: SB 109/79/NN)**

Applicants must be under 30 years of age at December 31, and possess

- (a) a 1st or 2nd class Honours degree in Metallurgy; or
- (b) an equivalent qualification acceptable to the Civil Service Commissioners.

Candidates must have at least 2 years' postgraduate experience in research or industry.

Exceptionally, applications may be considered from candidates over the age limits who have specialised experience.

Starting salary will be related to qualifications and experience.

The salary scale is under review with effect from April 1, 1979.

There are promotion prospects to Higher Scientific Officer £4,101 to £5,488, Senior Scientific Officer £5,154 to £6,898 and Principal Scientific Officer £6,609 to £8,461.

Please write or telephone for an application form quoting the appropriate job reference to the Civil Service Commission, Rosepark House, Upper Newtownards Road, Belfast BT4 3NR (telephone Dundonald 4585 ext 256). Completed forms must be returned to arrive not later than May 18, 1979. 652(A)

## UNIVERSITY COLLEGE LONDON

### Applications invited for post of RESEARCH ASSISTANT

to work on problems of microtubule assembly and its relationship to spindle formation and mitosis in the yeasts *Saccharomyces cerevisiae* and *Schizosaccharomyces pombe* under the supervision of Dr J. S. Hyams. Appointment will be for three years and successful applicant may register for a higher degree. Applicants should hold, or expect to obtain, a first or upper second class honours degree in Microbiology, Cell Biology, Biochemistry or related subject. Starting salary £3,410 per annum (under review) plus £502 London Allowance. Applications in form of curriculum vitae, giving names and addresses of two referees to Dr J. S. Hyams, Department of Botany and Microbiology, University College London, Gower Street, London WC1E 6BT, from whom further details may be obtained. Closing date May 24, 1979. 636(A)

## M. D. ANDERSON PROFESSOR IN PHYSICS

The University of Houston is seeking candidates for an M. D. Anderson Professor, an endowed chair, in the Department of Physics. The applicants should be established leaders in their field of physics. The successful candidate is expected to provide strong and constructive intellectual leadership not only to the Physics Department but also to the institution as a whole. General duties of this appointment will include both teaching and research.

The current departmental areas of research consist of condensed matter, intermediate energy, plasma, space, and theoretical physics.

Applicants should include a resume, a brief description of professional interests and goals, and the names and addresses of three or more references. Send applications to: C. W. Chu, Chairman, Search Committee, Department of Physics, University of Houston, Houston TX 77004. The University of Houston is an equal opportunity employer. W91(A)

## NATIONAL INSTITUTE FOR RESEARCH IN DAIRYING

(UNIVERSITY OF READING)

### NUTRITION DEPARTMENT

A graduate is required to participate in a programme of fundamental research into the physiological role of trace nutrient binders in milk and other foods. The work will be mainly concerned with the isolation, characterisation and comparative biochemistry of binding substances from milks of different mammalian species, in particular from bovine and human milk. The appointed person will work within a small group studying binding substances and will be expected to initiate and execute experimental work with a minimum of supervision.

Qualifications: First or Upper Second class Honours Degree in biochemistry or recently qualified Ph.D. Applicants with experience in protein chemistry and enzymology will be at an advantage.

Appointment will be as Scientific Officer (£2,839 to £4,415) or Higher Scientific Officer (£4,101 to £5,448) according to qualifications and experience. At least two years' relevant postgraduate experience is required for appointment as H.S.O. Non-contributory superannuation scheme.

Application forms are obtainable from the Secretary, NIRD, Shinfield, Reading RG2 9AT. Quote reference 79/15. 595(A)

## UNIVERSITY OF MALAYA

Applications are invited for the posts of

### LECTURER

in the following departments in the Faculty of Science:

#### DEPARTMENT OF BOTANY

Candidates must possess a higher degree in the field of Botany or Agriculture. Preference will be given to candidates who have a Ph.D. degree and experience in Tropical Crops.

#### DEPARTMENT OF GEOLOGY

In the field of Structural Geology/Rock Mechanics.

#### DEAN'S ESTABLISHMENT

The fields required are as follows: Scientific Method, Scientific teaching, logic, history of science in relation to Greek Science, Chinese Science, Islamic Science and Modern Science and philosophy of Science.

#### QUALIFICATIONS

Candidates for the appointments should possess at least: A Master's degree in the required field; or a Ph.D. in the required field.

**Salary Scale** (All inclusive): £3,602 by 168 to 3,939/4,107 by 168 to 4,443/4,780 by 280 to 6,182/Review Point/£6,462 by 336 to 6,799 per annum. The commencing salary for Lecturers with a Ph.D. degree shall be £4,107 per annum.

Further particulars and application forms are obtainable from the Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF.

The closing date for the receipt of applications is **May 31, 1979.** 664(A)

## AN DER FREIEN UNIVERSITÄT BERLIN IST FOLGENDE STELLE ZU BESETZEN

*Fachbereich 1—Natur- und sozialwissenschaftliche Grundlagenmedizin und medizinische Ökologie—Institut für Anatomie*

### PROFESSOR (C 4)

**Aufgabengebiet:** Vertretung des Faches Anatomie in Forschung und Lehre. Wissenschaftliche Arbeitsmöglichkeiten auf allen morphologischen Teilgebieten stehen zu Verfügung. **Einstellungsvoraussetzung:** \$ 13 BerIHG. Bewerbungen mit den üblichen Unterlagen sind innerhalb von 6 Wochen zu richten an den Fachbereich 1—Natur- und sozialwissenschaftliche Grundlagenmedizin und medizinische Ökologie—Gustav Meyer-Strasse 7, 1000 Berlin 33. W92(A)

## UNIVERSITY OF BRISTOL DEPARTMENT OF PHYSIOLOGY POSTGRADUATE RESEARCH ASSISTANT

to work within a small research group on cellular neurobiology of sensor and motor systems in crustaceans employing electrophysiological, pharmacological and computer techniques. The position is available for up to two years, at a starting salary of £3,38 per annum (scale under review).

Applications with curriculum vitae and names of two referees to Dr B. M. H. Bush, Department of Physiology, The University, Bristol BS8 1TD, by May 25, 1979. 599(A)

## Scientific Officer £2,839 – £4,415

Applications are invited for a pensionable post of Scientific Officer in the Department of Commerce, Industrial Science Division, which is located at 17 Antrim Road, Lisburn.

The successful candidate will assist in developing the Information Service of a Division which provides a wide range of technical services in Northern Ireland for Industry and Government. The duties will include answering technical enquiries extending over a wide field, particularly from industry; compilation of literature surveys, and provision of current awareness services. There will be particular emphasis on the use and application of computerised methods for information retrieval.

Applicants must be under 27 years of age on December 31, 1979 and have a degree, HNC/HND, or equivalent qualifications in chemistry or physics. Those hoping to qualify in the summer graduations may apply. A qualification in Information Science, or experience of technical information work and an aptitude for languages will be an advantage.

Exceptionally applications may be considered from candidates over the age limits who have specialised experience.

The Commissioners may decide to interview only those applicants who appear from the information available (including level of academic attainments and experience) to be best qualified.

There are promotion prospects to Higher Scientific Officer (£4,101–£5,448) Senior Scientific Officer (£5,154–£6,898) and Principal Scientific Officer (£6,609–£8,461).

Starting salary will be related to qualifications and experience.

The salary scale is under review with effect from April 1, 1979.

Please write or telephone for an application form quoting job reference SB 200/79/N to the Civil Service Commission, Rosepark House, Upper Newtownards Road, Belfast BT4 3NR (telephone Dundonald 4585 ext 256). Completed forms must be returned to arrive not later than May 17, 1979.

642(A)

**NORTHERN IRELAND  
CIVIL SERVICE**

## UNIVERSITY OF SIERRA LEONE

NJALA UNIVERSITY COLLEGE

Applications are invited for the post of

### LECTURER IN PHYSICAL CHEMISTRY

tenable from September 1, 1979. Candidates are required to have a good first degree in Chemistry and research and teaching experience in Physical Chemistry. The appointee will be required to teach Physical and General Chemistry up to B.Sc. General degree level; to instigate and supervise student projects, and participate in research within the Department. Salary scale:— Le4,488 to Le6,897 per annum. (£1 sterling = Le2.20). The British Government is unlikely to provide salary supplementation and associated benefits. Family passages; University Superannuation scheme or contract terms; annual leave; car loan negotiated; various allowances; part-furnished accommodation at reasonable rent. Detailed applications (2 copies) with curriculum vitae and naming three referees to be sent to Secretary, University of Sierra Leone, Private Mail Bag, Freetown, Sierra Leone, by June 23, 1979. Applicants resident in the UK should also send one copy to the Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further particulars may be obtained from either address.

670(A)

## UNIVERSITY OF DURHAM CHAIR IN GEOLOGY

Applications are invited for the from candidates with research interests in any of the main fields of Geology. The appointment will date from October 1, 1979 or such later date as may be arranged.

The vacancy arises from the appointment of Professor G. M. Brown F.R.S. as Director of the Institute of Geological Sciences.

The appointment will be made on the Professorial salary scale together with the usual pension arrangements.

Applications (three copies), including the names of three referees, must be submitted not later than June 5, 1979 to the Registrar and Secretary, Old Shire Hall, Durham DH1 3HP, from whom further particulars may be obtained.

605(A)

A position is available in the Department of Biochemistry, University of Alberta, Edmonton, T6G 2H7, beginning in the fall of 1979. Applicants should have a good background in DNA metabolism and DNA-drug interactions, both at the graduate and postdoctoral level. A strong background in physicochemical techniques is required for current studies on multistranded nucleic acids and their possible biological roles. Only Canadian Citizens may apply for this position. Please apply to Dr A. R. Morgan at the above address.

W73(A)

# Laser Scientists. Plasma Physics.

You will be joining a small experimental team to provide facilities for and collaborate with university users of the SRC Central Laser Facility. The experiments are primarily in laser driven implosion and compression of plasmas and laser plasma interactions. The work involves principally the development and maintenance of new measurement systems of an electronic or opto-electronic nature as well as assisting University research workers with the operation of the laser target facilities.

You should have a university degree in a relevant subject. Experience in pulse electronics, automated data recording or optics would be advantageous.

## Glass Laser Development.

You will be a member of a team that is responsible for the development and operation of the neodymium glass laser at the SRC Central Laser Facility. The work is mainly experimental and is associated with areas such as the development of improved laser oscillators, the investigation of pulse shaping techniques and the design of laser diagnostics. This post offers scope for an individual contribution in an area of applied physics where a sound knowledge of optics and laser physics is particularly appropriate.

You should have a university degree in a relevant subject.

The appointments will be made to the Scientific Officer grade and depending on qualifications and experience, salaries will be within the range £3,037-£4,724. Salaries are currently under review.

Contact Jane Griffiths in the Personnel Group on Abingdon (0235) 21900

Ext. 510 or write to her quoting reference VN.805.

Closing date for applications 18th May 1979.

614(A)

**RUTHERFORD  
Science Research Council**

Rutherford Laboratory, Chilton, Didcot,  
Oxfordshire OX11 0QX. Tel Abingdon 21900

## UNIVERSITY OF CAMBRIDGE DEPARTMENT OF PATHOLOGY

Applications are invited for a postdoctoral

### RESEARCH ASSISTANT (aged under 30)

on a project funded by the M.R.C. for an 8 month period to work on the Genetics of the Immune Response and in Tissue Culture Methods. Salary according to age. Applications in writing to The Superintendent, Department of Pathology, Tennis Court Road, Cambridge CB2 1QP.

627(A)

## Applied Mathematics and Theoretical Physics CAMBRIDGE UNIVERSITY

Applications invited for an Assistant Lectureship vacant on October 1, 1979. No restriction on research field, but strong applications from specialists in mechanics of solid materials are especially welcome. Teaching duties include giving two courses of lectures. Standard university salary scale. Appointment for three years initially. Further information available from Head of Department of Applied Mathematics and Theoretical Physics, Silver Street, Cambridge CB3 9EW. Applications required by May 31, 1979.

658(A)

**The POLYTECHNIC  
WOLVERHAMPTON**

# Research Assistants

Applications are invited for posts available for work on the following projects from 1 September 1979 or for work on a project specified by the applicant in one of the following areas of study:

## SOCIAL SCIENCE

1. The Psychology of Stuttering.
2. How Personality Factors Influence Role-taking and Outcome of Experimental Groups.

## SCIENCE

3. Educational Management Information Systems.
4. Function of Peroxisomes in Fat Metabolising Cells of Animals.
5. Hot Corrosion of Alloys in Coal-Fired Fluidised Combustion.

## ENGINEERING

6. The Development of a High-Strength Tool Geometry.
7. Optimum Machining Conditions for Reaction-Bonded Silicon Carbide.
8. Heat Transfer and Vibration in Heat Exchangers.

Appointments will be made in June and are normally for two or three years. Successful applicants will be expected to register for a higher degree where appropriate.

Salary from £3000 per annum.

Further details and application form (returnable by 7th June) from:  
'Personnel' (RA3), The Polytechnic,  
Wulfruna Street, Wolverhampton, WV1 1LY.  
(Telephone: 0902 27371 Ext. 94)

## IMPERIAL COLLEGE

### RESEARCH PHYSICIST

Applications are invited for a tenured post in High Energy Nuclear Physics Group of the Department of Physics. The successful candidate will be involved in particle physics research and will guide equipment development and design. This will necessitate working with both the Counter and Bubble Chamber sections of the Group and could involve measuring machine development, development of hybrid hardware for triggered bubble chamber experiments or development of detectors. Candidates with a research background outside particle physics will be considered. Starting salary will be on the research and analogous 1A scale £4,760 to £7,647 (including London allowance) according to suitability. Closing date May, 28 1979. Please apply to:

T. W. Dickson,  
Blackett Laboratory,  
Imperial College,  
London SW7 2AZ.

654(A)

## VETERINARY PATHOLOGISTS

Hazleton Laboratories, one of Europe's leading laboratories serving the Safety Evaluation needs of the chemical and pharmaceutical industries, require veterinarians experienced or interested in the rapidly developing field of laboratory animal pathology.

Experienced candidates would be expected to have at least 2-3 years experience in pathology, preferably in a commercial appointment. New graduates or post-graduates without previous experience in Pathology would be given suitable in-house training and encouraged to attend outside courses and seminars.

Based in Harrogate within easy access of the Yorkshire Dales, the posts carry generous remuneration, assistance with re-location, and other fringe benefits to be expected from an expanding and progressive company.

To find out more about the posts, the company and Harrogate please telephone:

Barbara Grant  
Hazleton Laboratories Europe Limited  
Otley Road  
HARROGATE.

Telephone Harrogate (0423) 67265.

615(A)

LABORATORIES EUROPE LTD

## UNIVERSITY OF LONDON

### KING'S COLLEGE SCHOOL OF HUMAN

### ENVIRONMENTAL STUDIES

Applications are invited for a

### LECTURESHIP

in Human Environmental Studies. The applicants should have a knowledge of geomorphology, climatology and other aspects of physical geography and be able to relate these to environmental issues. Cartographic and statistical qualifications are also required and a background in ecology would be advantageous.

Current salary scale £3,883 to £7,754 per annum (under review) plus £502 per annum London Allowance. The starting salary will be at an appropriate point on the scale. Universities Superannuation Scheme contributions would be payable.

Application forms and further particulars are available from the Assistant Registrar, King's College London, Strand, LONDON WC2R 2LS and should be returned to him in triplicate to reach him no later than May 15, quoting ref. 191675 N.

606(A)

## ROYAL POSTGRADUATE

### MEDICAL SCHOOL ENDOCRINE UNIT

### RESEARCH OFFICER

required for studies on the regulation of Vitamin D metabolism. Work will involve cell culture, chromatography studies and in vivo experiments.

Applicants must have or expect to be awarded a first class or upper second class honours degree in an appropriate subject. There may be an opportunity for Ph.D. registration for a suitable candidate.

Starting salary £3,410 plus £45 London Allowance rising on scale 1 for Research and Analogous Staff Scales currently under review. The appointment is for three years supported by the Medical Research Council.

For further details and an informal discussion please phone Professor MacIntyre on 01-743 2030, extension 457.

Application forms may be obtained from the Personnel Office, Royal Postgraduate Medical School, 150 D Cane Road, London W12 0HS quoting reference number 4/210/N.

613(A)

## UNIVERSITY OF SOUTHAMPTON

### MEDICAL ONCOLOGY UNIT

Applications are invited for the position of Postdoctoral Research Fellow in the above Unit. The person appointed will work on the isolation of cytoskeletal proteins and their interaction with the cell surface, in close cooperation with a group interested in cell adhesion and with others interested in clinical aspects of cancer research. Applicants should either be about to obtain or have recently obtained a Ph.D. in Biochemistry or some related discipline. Experience of protein biochemistry, membrane biochemistry or immunology would be advantageous. The appointment will be for one year in the first instance, renewable annually for at least three years.

Salary Range: £3,883 to £4,822 per annum (under review). U.S.S. benefits.

Applications giving date of birth, curriculum vitae and the names and addresses of two referees, should be sent to Mrs P. Vaughan-Smith, The University, Southampton SO9 5NH, not later than May 18, 1979. Please quote reference 1069/R/N.

598(A)

# UNIVERSITY OF NAIROBI Kenya

Applications are invited for the following posts in the

## DEPARTMENT OF PHYSICS ASSOCIATE PROFESSOR

Applicants must possess a PhD in Physics with considerable years of University teaching and substantial research experience as evidenced by publications in internationally reputable journals. Active areas of research in the Department include Solid State Physics, Applied Geophysics, Paleomagnetism, Electronics and Theoretical Physics.

### SENIOR LECTURER

Applicants must possess a PhD in Physics with considerable years of University teaching and research experience as evidenced by publications in reputable journals. Specialisation in Applied Geophysics, Solid State Physics, Theoretical Physics, Electronics or Paleomagnetism will be an added advantage.

Salary scales: Associate Professor K£3,864 to £4,488 per annum, Senior Lecturer K£2,988 to £3,984 per annum (K£1=£1.28 sterling). The British Government may supplement salaries in range £5,430 to £5,784 per annum (sterling) for married appointees and £3,648 to £3,648 to £3,876 per annum (sterling) for single appointees (reviewed annually and normally free from tax) and provide children's education allowances and holiday visit passages. Family passages; S.S.S.F. or F.S.S.U.; non-contributory medical scheme; subsidised housing or housing allowance. Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct, to Registrar (Recruitment and Training), University of Nairobi, P. O. Box 30197, Nairobi, Kenya by June 24, 1979. Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 679(A)

## UNIVERSITY OF OXFORD POSTDOCTORAL RESEARCH ASSISTANT AND TECHNICIAN

required for research into the regulation of branched chain 2-oxo acid dehydrogenase complex, branched chain amino acid catabolism and into disorders of branched-chain amino acid metabolism. The posts are for three years from a mutually convenient date in 1979 and are funded by the Medical Research Council. The postdoctoral research assistant should have experience in enzymology and protein chemistry and possess or expect a Ph.D. or equivalent degree. The technician should have a degree in biochemistry (or a related subject) or possess suitable laboratory experience. Starting salaries up to £4,382 (research assistant) and £3,930 (technician) on scales in operation on March 1, 1979.

Applications including the names of two referees to Professor P. J. Randle, Department of Clinical Biochemistry, Radcliffe Infirmary, Oxford OX2 6HE from whom further details may be obtained. 659(A)

Postdoctoral/Research Associate position available immediately to work on the cloning of soybean leghaemoglobin and other plant genes obligatory for symbiosis with *Rhizobium*. Experience in the area of nucleic acid, biochemistry and microbiology desired. Salary commensurate with experience. Send résumé and letters of reference to Dr D. P. S. Verma, Department of Biology, McGill University, Montreal, Quebec, Canada. W90(A)

# Materials Scientist for the Oil Industry

The Esso Research Centre at Abingdon — the company's largest technical establishment in Europe — specialises in research into fuels, lubricants and additives and also provides a technical service to the refinery, marketing and transportation operations of the company.

We are shortly taking delivery of our first scanning electron microscope with microprobe analyser which will form the basis for an important new materials science facility for Esso in Europe.

We are looking for a Materials Scientist to take charge of the setting-up of this new facility and quickly integrate it with existing and future research programmes.

Aged 30-40 you should have a degree, preferably in materials science or metallurgy and at least five years' experience in the use and application of S.E.M. and other surface analytical techniques. Ideally this experience would have been in the petroleum industry or a related technical field such as Tribology.

A key attribute will be your ability to represent the potential of surface analytical techniques to customers and to establish a comprehensive service which meets Esso's future needs.

For this senior and challenging position a competitive salary will be supplemented by a full range of benefits, and generous relocation assistance, where appropriate, to this attractive rural area — just an hour away from London and only twenty minutes from Oxford.

Please write, with full details, to D.P. Sweeney, Employee Relations Service, Esso Research Centre, Abingdon, Oxon OX13 6AE, or phone him on: Abingdon 21600.

## RESEARCH

681(A)

## The University of Sussex TEMPORARY LECTURER IN HUMAN SCIENCES

One full-time, or two part-time, posts from October 1, 1979 for two years, in the School of Cultural and Community Studies. Applicants should be competent to take prime responsibility for the teaching of courses in two or more of the following areas: Human Ecology, Biosocial Anthropology, Human Prehistory and Primate Biology.

Salary will be on the Lecturer scale (full-time scale from 1.10.79: £3,975 to £8,250 per annum, under review) plus U.S.S.

Further particulars and application form, returnable by May 18, 1979, obtainable from the Establishment Section, Office of Arts and Social Studies, Arts Building, University of Sussex, BRIGHTON BN1 9QN (Brighton 606755, ext. 1050, Miss Pratt) quoting reference 034/N. 639(A)

## UNIVERSITY OF OTAGO Dunedin, New Zealand CHAIR OF PHARMACOLOGY

The University Council invites applications from medical or science graduates for appointment to the Chair of Pharmacology at present occupied by Professor F. N. Fastier who is retiring in early 1980.

Professorial salaries which are regularly reviewed, are paid within the following ranges:—

Medical NZ\$30,365 to NZ\$33,865 per annum.

Science NZ\$23,865 to NZ\$29,865 per annum.

(Both rates inclusive of NZ\$365 per annum cost-of-living allowance).

Further particulars are available from the Secretary General, Association of Commonwealth Universities (Apts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University.

Applications close on June 30, 1979. 610(A)

## AGRICULTURAL RESEARCH COUNCIL FOOD RESEARCH INSTITUTE

*Chemistry and Biochemistry Division*  
(Biopolymers and Physical Methods Groups)

### PROTEIN BIOCHEMIST/CHEMIST PHYSICAL CHEMIST/COLLOID SCIENTIST BIOPHYSICIST/PHYSICAL BIOCHEMIST

A **PROTEIN BIOCHEMIST OR CHEMIST** is required to initiate a programme of research into the structure and properties of food proteins—especially those of vegetable origin. The person appointed will be expected to lead a small research team and to develop techniques to study the reactions of food proteins that are important in determining the quality of food. (Ref: 78/13).

A **PHYSICAL CHEMIST OR COLLOID SCIENTIST** is required to initiate a programme of research to define the physical properties of dispersions and gels in food and to study the surface properties and interfacial characteristics of food systems. The person appointed is expected to lead a small research team and to develop modern techniques to study temperature-dependent changes and factors affecting the stability of multicomponent systems in food. (Ref: 78/8).

A **BIOPHYSICIST OR PHYSICAL BIOCHEMIST** is required to lead a small research team to study the behaviour of food biopolymers in solution or dispersion and in gels. The person appointed is expected to develop modern physical and spectroscopic techniques to study the dynamics of changes and molecular interactions in systems containing proteins and polysaccharides. A broad background in the use of physical methods in biology and familiarity with the latest developments in spectroscopic techniques is required. (Ref: 76/10).

It is intended that the persons appointed to the above posts will work in close collaboration. A broad approach is required and the ability to extrapolate from basic studies to practical problems will be an advantage.

#### Qualifications

For appointment as Higher Scientific Officer: a First or Upper Second Class Honours Degree in an appropriate subject, at least two years' relevant post-graduate experience and preferably a Ph.D. degree, or equivalent experience.

For appointment as Senior Scientific Officer: as for Higher Scientific Officer but with at least four years' relevant post-graduate experience.

Candidates with several years' postdoctoral experience and an established research record in the relevant field will be considered for appointment as Principal Scientific Officer.

#### Salary (under review)

Principal Scientific Officer £6,609—£8,461  
Senior Scientific Officer £5,154—£6,898  
Higher Scientific Officer £4,101—£5,448

(Starting salary according to experience).

Non-contributory superannuation scheme at age 18 years and over.

Five-day week and flexible working hours scheme operated.

**Application form and further particulars from the Secretary, Food Research Institute, Colney Lane, Norwich NR4 7UA quoting appropriate reference. Closing date: May 21, 1979.**

## CONFERENCES

### CALL FOR ABSTRACTS BIOPHYSICAL DISCUSSIONS Second Discussion—May 1980 PROTEINS AND NUCLEOPROTEINS: STRUCTURE, DYNAMICS AND ASSEMBLY

The Biophysical Society will hold its 2nd Biophysical Discussion at Airlie House, Airlie, Virginia (near Washington, D.C.) on May 18-21, 1980. This Discussion will consider recent advances in understanding the principles of macromolecular structure and dynamics. Sessions will be devoted to: elucidation of structure by diffraction and spectroscopic methods; nature of forces stabilizing macromolecular structure; fluctuations in macromolecular structures; and mechanisms of folding and assembly. Experimental systems to be discussed include proteins, viruses, and organelles involving protein-nucleic acid interactions.

Prior to the meeting, all participants will receive a study book containing the full Discussion papers and poster abstracts. There will be no formal presentation of papers at the meeting, only a five-minute reminder followed by open discussion. A \$175 fee will cover registration, three days' room and board, the study book, and the final proceedings volume.

Papers submitted for the Organizing Committee's consideration are due as follows:

July 16, 1979—Preliminary abstracts (<300 words, to be reviewed and selected by August 1st)  
December 1, 1979—Complete manuscripts (to be refereed and selected by mid-January)

The full edited proceedings of ca. 500 pp, will be published in hardback by Rockefeller University Press (\$20 prepublication, \$30 after October 1980). Identical text will be received by *Biophysical Journal* subscribers (1980 subscription, 12 issues, \$150). For these publications, remit to Order Service, Rockefeller University Press, P.O. Box 5108, New York, N.Y. 10249, USA.

For further information contact Valerie Parsegian, Executive Secretary, Biophysical Discussions, P.O. Box 30239, Bethesda, Maryland 20014, USA. Phone (202) 362-8184. W93(C)

Quekett Microscopical Club Lecture. Dr James Dyson, Sc.D., F.R.S., will speak on 'Interference and Image Shearing Microscopy' at 6.30 p.m. on Tuesday, May 8, at the British Museum (Natural History), Cromwell Road, South Kensington, London SW7 5BD. All Club members and visitors are welcome. 563(C)

## STUDENTSHIPS

### UNIVERSITY OF OXFORD M.R.C. RESEARCH STUDENTSHIP

Applications are invited from biochemists, chemists or physiologists for a 3 year studentship to commence in October 1979. The successful candidate will register for a D. Phil and pursue research into the chemistry, kinetics and mechanism of enzymes involved in human cataract formation, in particular aldose reductase in diabetes.

Applications together with the names and addresses of three referees, and requests for further information should be sent to Dr James Crabbe,

University of Oxford,  
Nuffield Laboratory of  
Ophthalmology,  
Walton Street,  
Oxford OX2 6AW. 621(F)

### UNIVERSITY OF EAST ANGLIA BP RESEARCH CENTRE S.R.C. C.A.S.E. STUDENTSHIP

Infrared Spectroscopy of Reaction Intermediates on Catalyst Surfaces in Propylene Ammoxidation. S.R.C. Research Studentship plus £100 plus fees available from October 1, 1979.

Apply to Professor N. Sheppard, F.R.S., School of Chemical Sciences, University of East Anglia, Norwich NR4 7TJ. 648(F)

## UNIVERSITY OF CAMBRIDGE

### DEPARTMENTS OF APPLIED BIOLOGY AND MINERALOGY N.E.R.C./C.A.S.E. RESEARCH STUDENTSHIP

Applications invited from scientists holding or expecting to obtain a good honours degree for a project on the identification, origin and reaction of asbestos waste in ground-water systems, starting October 1979.

Further details from Dr. C. V. Jeans, Department of Applied Biology, Pembroke Street, Cambridge CB2 3DX. 624(F)

### THE MIDDLESEX HOSPITAL MEDICAL SCHOOL (University of London) MEDICAL RESEARCH COUNCIL STUDENTSHIP

Applications are invited from a candidate with a good honours degree to work on biophysical aspects of cell-substratum interactions or membrane fusion. Applications, including curriculum vitae, and the names of two referees, to Dr David Gingell, Department of Biology as Applied to Medicine, The Middlesex Hospital Medical School, London W1P 6DB. 647(F)

### UNIVERSITY OF EAST ANGLIA Norwich S.R.C. C.A.S.E. STUDENTSHIPS

S.R.C. CASE awards will be tenable at the University of East Anglia from October 1, 1979 in support of research in the following fields:—

- a) in cooperation with the 'Glasshouse Crops Research Institute' 1. "The role of spiders in checking aphid outbreaks in cereals" Supervisors: Professor A. F. G. Dixon/Dr. K. D. Sunderland.
2. "Aphid-specific natural enemies of cereal aphids" Supervisors: Professor A. F. G. Dixon/Mr. R. J. Chambers.
- b) in cooperation with the Forestry Commission "Control of polymorphism in green spruce aphid" Supervisors: Professor A. F. G. Dixon/Dr. C. I. Carter.
- c) in cooperation with the Food Research Institute, Norwich "Infection of carrot roots by *Sclerotinia sclerotiorum*" Supervisors: Dr. B. G. Lewis/Dr. C. Dennis.

Applicants should possess or expect to obtain a First or Upper Second Class degree and should write to Professor A. F. G. Dixon, Dean School of Biological Sciences, University of East Anglia, Norwich NR4 7TJ. Applications together with a curriculum vitae and the names of two referees should arrive by May 18 1979. 657(F)

### M.R.C. PNEUMOCONIOSIS UNIT

Llandough Hospital  
PENARTH,  
SOUTH GLAMORGAN  
CF6 1XW

Applications are invited for a MRC Research Studentship from those who have, or expect to obtain this year a good honours degree, M.Sc. or equivalent qualification in physics, electrical engineering, mathematics, or statistics. The successful candidate will register for a Ph.D.

Projects include instrument development in respiratory physiology and the study of the statistical aspects of dose response curves for hazardous substances.

Further information and application forms may be obtained from the Assistant Administrative Officer. 619(F)

## STUDENTSHIPS—continued

DEPARTMENT OF PHYSIOLOGY  
UNIVERSITY OF  
LIVERPOOL  
M.R.C.  
RESEARCH STUDENTSHIP

Applications are invited for an M.R.C. Research Studentship in the Department of Physiology. Candidates should have, or expect to obtain this year, a good honours degree in Physiology or a related subject. Experience in some aspect of histology and cell biology would be an advantage. The successful applicant will join a group working on a development and application of immunocytochemical methods to study the cellular origins, chemical relationships and physiological roles of gut hormones and neuropeptides. He/she will be expected to register for a Ph.D.

Applications, together with the names of two referees, should be received not later than June 7, 1979, by the Registrar, The University, P. O. Box 147, Liverpool, L69 3BX. Quote Ref. RV/583/N 674(F)

UNIVERSITY OF LEICESTER  
DEPARTMENT OF ZOOLOGY  
SCHOOL OF  
BIOLOGICAL SCIENCES  
POSTGRADUATE

## RESEARCH STUDENTSHIP

Applications are invited for a postgraduate research studentship financed by the Medical Research Council, and tenable for three years for the study of regulation and determination of spatial patterns of cellular differentiation in arthropods.

The study would be of particular interest to those with some interest and background in Developmental, Cell or Neurobiology, although candidates with other qualifications will be considered.

Applicants should send a curriculum vitae and names and addresses of 2 referees to Dr P. M. J. Shelton, Department of Zoology, University of Leicester, Leicester LE1 7RH, as soon as possible. 514(F)

UNIVERSITY OF  
EDINBURGH  
M.Sc. COURSE  
on The Physics and Technology  
or Amorphous Materials

(a joint course with the Universities of Dundee and Glasgow) 1 year full-time from October 8, 1978

Main topics include: Structure; Preparation; Characterisation; Basic Theory; Electronic and Optical Properties; Thermal and Mechanical Properties; Magnetism; Glasses and the Vitreous State; Technological Applications, including Solar Energy Conversion and Applications in Solid State Electronics. The final term will be devoted to an individual research project.

Entry qualifications: Normally an honours degree or its equivalent in Physics, Electrical Engineering, Chemistry or a Materials Science.

Grants: SRC Advanced Course Studentships are available for applicants with appropriate qualifications. Further information from: Dr A. E. Owen, Department of Electrical Engineering, King's Buildings, University of Edinburgh, Edinburgh, EH9 3JL, Scotland, U.K. 673(D)

UNIVERSITY OF GLASGOW  
DEPARTMENT OF ORGANIC  
CHEMISTRY  
POSTDOCTORAL  
FELLOWSHIP IN  
BIOORGANIC CHEMISTRY

Available for two years from October 1, 1979 to study amino-acid metabolism in plant tissue cultures and micro-organisms. SRC-sponsored. Applicants should have strong background in organic synthesis. Experience with radio-isotopes and micro-organisms or plants an advantage but not essential. Starting salary in range £3,883 to £4,382 per annum (1A, Research and Analogous Staff salary scales—currently under review). Applications with names of two referees to Professor K. H. Overton, Chemistry Department, University of Glasgow, Glasgow, G12 8QQ. In reply please quote Ref. Number 4436M. 596(E)

INSTITUTE OF  
CANCER RESEARCH  
(Chester Beatty Research  
Institute)

MASS SPECTROMETRY—  
DRUG METABOLISM GROUP

A three-year postdoctoral fellowship will be available later in 1979 associated with a multidisciplinary group studying the metabolism of anticancer drugs in relation to mode of action, design of new drugs, and improvement of clinical use. In vitro, animal, and human studies are in progress. A major current emphasis concerns the study of a group of drugs which are in current clinical use for the treatment of disseminated breast cancer. The appointee will be responsible for that part of the Group programme which involves the use of desmolase (cholesterol side chain degradation) aromatase, and estrogen receptors in developing structure-activity relationships. Applicants should have research training in biochemistry, preferably with an interest and experience in enzyme manipulation, and not more than two years' postdoctoral experience. The fellowship, which is superannuated (U.S.S.), will have an initial salary (presently under review) of not less than £4,910 per annum (including London Allowance).

Applications, including a full curriculum vitae, in duplicate and with the names of two referees should be sent as soon as possible to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref. 300/G/5. 649(E)

## COURSES

UNIVERSITY OF SOUTHAMPTON  
Department of Chemistry

## M.Sc. Course in Electrochemical Science

Applications from candidates with a good honours degree are invited for this 12 month course, which provides a comprehensive training in the methodology of modern electrochemical research and the applications of electrochemistry in industry. The course, which commences in October 1979, has been approved by the Science Research Council, and a number of studentships will be available. Further details of the course and application forms can be obtained from Dr L. M. Peter, Department of Chemistry, The University, Southampton, SO9 5NH/N. 656(D)

## FELLOWSHIPS

QUEEN'S UNIVERSITY  
Kingston, Ontario

Applications are invited for a M.R.C. supported postdoctoral fellowship to work with Dr B. T. Eaton on the study of arbovirus persistence in mosquito cells. The appointment is available for two years and the initial salary is \$12,000 per annum. Prospective or recent Ph.D. graduates should send their curriculum vitae and the names of two referees to Dr Eaton, Department of Microbiology and Immunology, Queen's University, Kingston, Ontario K7L 3N6, Canada. W80(E)

NATIONAL INSTITUTE FOR  
MEDICAL RESEARCH  
POSTDOCTORAL  
RESEARCH FELLOWSHIP

Applications are invited from suitably qualified biochemists, pharmacologists or neurochemists to join a team who are investigating the biochemical and pharmacological properties of muscarinic acetylcholine receptors in the Division of Molecular Pharmacology. This position is available immediately and will be renewable on an annual basis for at least two years. The salary will be the same as that of a member of the Medical Research Council scientific staff of comparable age and experience.

Applicants should send curriculum vitae and the names of two referees to Dr N. J. M. Birdsall, Division of Molecular Pharmacology, National Institute for Medical Research, Mill Hill, London NW7 1AA. 620(E)

THE UNIVERSITY OF  
MANCHESTER  
POSTDOCTORAL  
RESEARCH FELLOWSHIP IN  
OFFSHORE ENGINEERING

Applications are invited for research into the behaviour of offshore piles subjected to cyclic loading using the 700g tonne centrifuge. The appointment is for 2½ years commencing September 1, 1979 at a salary of up to £6,080 per annum (under review). Superannuation. Full particulars of the post are obtainable from Mrs. A. C. Davies, Simon Engineering Laboratories, The University, Brunswick Street, Manchester. 655(E)

UNIVERSITY OF SUSSEX  
SCHOOL OF  
MOLECULAR SCIENCES  
POSTDOCTORAL  
RESEARCH FELLOWSHIP

Applications are invited for an S.R.C. Research Fellowship in the School of Molecular Sciences to work on Cycloadditions to Silyl-protected Polyacetylenes and Polyenes in collaboration with Dr D. R. M. Walton. The position will become available on October 1, 1979 and is within the usual Research Fellow 1A salary range. The appointment is for one year in the first instance, renewable for a further year. Small-scale preparative research experience in organometallic/natural product chemistry is desirable, coupled with a genuine interest in p.m.o. calculations.

Applications, accompanied by the names of two referees should be sent as soon as possible to Mr R. W. Bott, Sub-dean, School of Molecular Sciences, University of Sussex, BN1 9QJ. 638(E)

M.Sc. BRAIN STUDIES  
BRUNEL UNIVERSITY

Two-year part-time course in Cybernetics, Experimental Psychology and Neurophysiology. Entries October 1979 and October 1981.

Applicants should have 1st or 2nd class honours degree in a biological, medical or mathematical subject. Details from Dr R. C. Elliott, School of Biological Sciences, Brunel University, Uxbridge, Middlesex. 609(D)

MODERN TECHNIQUES  
IN CENTRIFUGATION  
September 2-7, 1979  
UNIVERSITY OF ESSEX

This is a workshop course designed to give participants practical experience of the newer centrifugation techniques now available. Participants will be able to use a wide variety of centrifuges and rotors including vertical rotors. The practical sessions will be complemented by a series of lectures and discussion groups covering topics of current interest. For further information contact the Liaison Officer (N), University of Essex, Wivenhoe Park, Colchester, CO4 3SQ (Tel. Colchester 862286, ext. 2375) 623(D)

BIRKBECK COLLEGE  
(University of London)

M.Sc.  
NATURAL ENVIRONMENTS  
AND PLANT GROWTH  
An integrated part-time EVENING  
COURSE in Soil Hydrology,  
Microclimatology and Plant  
Ecology

The M.Sc. Natural Environments and Plant Growth consists of a course of lectures, laboratory practicals and field-work extending over two academic years of part-time study and is given within the departments of Geography and Botany. Three modules are offered: Boundary Layer and Plant Canopy Microclimatic Environment; Soil Hydrological Environment; Environment and the Growth and Development of Plants.

Application forms and further details may be obtained from: The Secretary, Department of Geography, Birkbeck College, 7-15 Gresse Street, London W1P 1PA. 662(D)

## FELLOWSHIPS—continued

★ UNIVERSITY OF GLASGOW  
DEPARTMENT OF  
CHEMISTRY  
POSTDOCTORAL  
FELLOWSHIP

The above position is available under an M.R.C. project grant in respect of the determination of the structure of a bacterial chloramphenicol acetyl transferase at atomic resolution. This study is well advanced and the post is open to applicants with experience in crystallography. Starting salary will be within Range 1A of the salary scale for Research and Analogous Staff, £3,883 to £4,382, depending on age and experience.

Further particulars are available from Dr I. D. A. Swan, Department of Chemistry, University of Glasgow, Glasgow G12 8QQ, to whom applications, together with a curriculum vitae and the names of two referees, should be addressed.

In reply please quote Ref. No. 4325/1. 629(E)

## ASSISTANTSHIPS

CITY OF LONDON  
POLYTECHNIC  
DEPARTMENT OF BIOLOGICAL  
SCIENCES  
RESEARCH  
ASSISTANTSHIPS (2)

Applications are invited for two Research Assistants to work on the following projects:

1. To study bacteria from anaerobic environments, their interactions and effects on metal corrosion and the influence of inhibitors. The project will include adsorption studies, involving the use of the scanning electron microscope and radioactive tracer techniques. Reference number 79/29.
2. The regulation of gene expression during muscle differentiation with particular emphasis on a study of muscle nuclei. Applicants should have a background in biochemistry or Cell Biology. Reference number 79/28.

The appointments will be tenable for two years in the first instance and will be extended to three on satisfactory completion of the first two years.

The salary scale for Research Assistants is £2,613 to £2,700 to £2,787 plus London Allowance of £474 per annum.

Please apply in writing, giving full curriculum vitae and the names and addresses of two referees to the Staff Records Officer, City of London Polytechnic, 117 Houndsditch, London EC3A 7BU. Please quote the appropriate reference number.

663(P)

UNIVERSITY OF ABERDEEN  
DEPARTMENT OF ZOOLOGY  
M.R.C. RESEARCH  
ASSISTANTSHIP

Applications are invited for a Research Assistant to examine the relationship between surface-bound antibody and nutrient absorption in tapeworms. Candidates should have an Honours degree in either Immunology or Biochemistry (with experience in immunology techniques).

The appointment is tenable until April 30, 1981 from an early date, to be arranged.

Salary within Range 1B, £3,384 to £3,883 per annum (under review), with appropriate placing.

Further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by May 25, 1979. 622(P)

UNIVERSITY OF  
CAMBRIDGE

DEPARTMENT OF BOTANY  
RESEARCH IN GENETICS

Applications are invited for a postdoctoral research assistantship to study aspects of genetic recombination using fungal spore colour mutants. The appointment is supported by the S.R.C. and is for two years. Starting salary not less than £3,883 per annum. Apply to Dr. H. L. K. Whitehouse, Botany School, Downing Street, Cambridge CB2 3EA, giving the names of two referees. 653(P)

## MISCELLANEOUS

Dr Philippe KOURILSKY of the Unité de Génie Génétique, Institut Pasteur, Paris, will address the Annual Meeting of the Louis Rapkine Association on 'Génie Génétique—Problèmes et Perspectives' Friday, May 11, 1979 at 6 p.m. at the French Institute, Queensberry Place, London SW7. Admission free. 625(J)

## SYMPOSIA

SYMPOSIUM ON  
REPRODUCTIVE LOSS

The tenth annual New York State Health Department Birth Defects Symposium will be held in Albany, New York on October 29 to 31, 1979 in the Rockefeller Empire State Plaza Convention Center.

Address Inquiries to:  
Ian H. Porter, M.D.,  
Director, Birth Defects Institute,  
New York State Health Dept.  
Room 1917,  
Tower Building,  
Rockefeller Empire State Plaza,  
Albany, New York 12237.

W88(N)

FIFTH EMBO  
ANNUAL SYMPOSIUM

NUCLEIC  
ACID-PROTEIN  
INTERACTIONS

October 12–15 inclusive  
EMBL Heidelberg

In addition to members of the Organising Committee invited speakers include: J. Abelson (La Jolla); T. Bickle (Basel); H. Bujard (Heidelberg); P. Chambon (Strasbourg); R. Flavell (Amsterdam); C. Guthrie (San Francisco); S. Harrison (Harvard); C. Helene (Orléans); H. Hoffmann-Berling (Heidelberg); A. Landy (Brown); A. McPherson (Pennsylvania); M. Ptashne (Harvard); M. T. Record (Madison); H. Saedler (Freiburg); A. Schmitz (Geneva); J. Sperling (Rehovot); G. Stöffler (Berlin); F. W. Studier (Brookhaven); E. Vinuela (Madrid); J. C. Wang (Harvard); W. Wintermeyer (Munich); C. Yanofsky (Stanford).

The eight Plenary Sessions will cover Model Systems; Viruses; Chromatin; Polymerases; Regulatory Signals on DNA; Cleaving, Processing and Modifying Nucleic Acids; Ribosomes and tRNA; New Frontiers.

The Symposium will be held at the European Molecular Biology Laboratory Heidelberg with registration on Thursday October 11. Plenary sessions will be held in the mornings and afternoons of October 12-15 inclusive. The Symposium banquet will be held on the evening of October 15. Poster sessions will be arranged; applicants wishing to present a poster should submit a title and an abstract of 1-2 pages. Participants will be accommodated in two hotels in downtown Heidelberg, and transportation to the meeting will be arranged.

The registration fee is DM 80,— and includes daily lunches and the banquet but neither hotel charges nor evening meals.

Applications including a curriculum vitae should be sent to Dr. J. Tooze, Executive Secretary, European Molecular Biology Organisation, Postfach 1022.40, 69 Heidelberg 1, FRG, by May 31, 1979. Since the number of participants is limited to 200 the Organising Committee will notify those who have been accepted in August.

Organising Committee: D. Crothers (Yale); J.-P. Ebel (Strasbourg); A. Klug (Cambridge); C. Kurland (Uppsala, Chairman); J. Miller (Geneva); H. Schaller (Heidelberg); J. Tooze (Heidelberg, Secretary); C. Weissmann (Zürich).

## Happy Endings.

Your DNA research should have a happy ending. That's why Miles has developed enzymes that cleave and splice DNA easily and accurately.

All of our restriction nucleases—such as *Eco* RI—specifically cleave DNA within certain well-defined base sequences. And to make sure you're happy with the cleaved ends, we include a sample of lambda DNA for verification of enzyme activity ... so you never risk your research DNA. The results of our stringent specification tests are reported on the chemical

credential that accompanies each order. No surprises, no mystery.

And, for recombinant DNA, we have terminal transferase to add dA and dT segments and DNA ligase to splice fragments together.

Restriction nucleases, terminal transferase, DNA ligase. Miles enzymes for happy endings ... and beginnings.

Please supply more information about:

- ☐ Restriction nucleases    ☐ DNA ligase    ☐ Terminal transferase  
☐ Please send a current Miles Biochemical Catalog.

## Production plant for enzymes completed

Penzberg 11/10/78 - The Boehringer Mannheim GmbH has completed the third phase of construction of the new, most modern, production plant for analytical biochemicals at Penzberg/Bavaria. Within 7 years the largest technical manufacturing facilities have been erected. Here 420 coworkers produce biochemicals needed by scientists all over the world.

Biochemists know that, while it is possible to produce highly purified biochemicals in small quantities, it is very difficult to scale up to large quantities and maintain that high level of integrity. Boehringer Mannheim, with its most modern equipment and technology, has the capability of offering the same high quality, as well as

# MIX AND SPIN PERCOLL™

 **DENSITY  
MARKER  
BEADS**  
**NOW AVAILABLE**  
for calibration of gradients of Percoll

Now centrifugation is simpler,  
quicker and gives much greater resolution  
than you ever thought was possible.

- Self-generating gradients in 30 minutes or less
- Isoosmotic throughout the gradient
- Non-toxic to cells and viruses
- Does not interfere with enzyme assays or quench radioactivity
- Low viscosity for rapid isopycnic or rate zonal separations
- Suitable for cells, viruses and subcellular particles

**Guide to authors**

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

**Manuscripts** may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible;  $\exp(a)$  is preferred to  $e^a$  if 'a' is more than one character.

**References** are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

- (i) only one reference number need be used if the reference is to several papers by identical authors.
- (ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

**Artwork** should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

*Nature's* publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976)

## Steady-State Enzyme Kinetics

Stanley Ainsworth

Identifies the basic ideas of the subject for the graduate and advanced undergraduate student, and familiarises the reader with them so that they may then be applied to any problem likely to be encountered. Although it cannot altogether avoid mathematical presentation, almost all the equations used require only an elementary acquaintance with algebraic manipulation. Moreover the arguments themselves are presented as fully as possible to enable the reader to progress easily from each stage to the next.

## Wasted talent is wasted opportunity

THE Conservative and Unionist Party has been elected to govern the United Kingdom, with Mrs Thatcher as Prime Minister. The election was fought almost entirely on economic issues, and even on these the new government communicated little more than an intention. (We heard nothing about how much income tax would be cut, or what rise in value added tax would be necessary to pay for it, except for Labour's own, presumably biased, calculations.) Of science we have heard nothing—except on environmental issues from the Ecology Party, and on nuclear power from the Liberals.

We hope that the new government will recognise the central importance of science—and basic science, at that—to the economy. In opposition, the Conservatives have frequently called attention to 'wealth creation', which it says Labour has ignored. The Conservatives appear prepared to increase social inequalities (by redistributing the tax burden) and risk confrontation with organised labour (by introducing new legislation and cutting 'lame duck' industrial support grants). But are they prepared to invest in science? It is undeniable that science is increasingly the true source of wealth, now that the days of empire and exploitation are receding. President Carter has recognised this, with his constant calls to Congress for an increase in science funding. And West Germany has recognised it, with a massive increase in funding for its science ministry in this year's budget.

Shirley Williams, the outgoing Secretary of State for Education and Science, had also recognised it, managing to wrest a few extra millions for the research councils this year. But will the Tories recognise it? We hope they will have the vision to do so, particularly with Britain's first scientist (Mrs Thatcher was a chemist) as Prime Minister. Mrs Williams' balm merely alleviated the worst of a long history of financial stringency in the research councils, and there is a great deal of slack to be taken up—not least in the replacement of aging equipment like spectrometers and microscopes, or proper investment in Britain's great scientific successes like molecular biology (where with genetic engineering there is enormous economic potential) or even the less obviously economic radio and high energy astronomy. Great international centres of excellence have a galvanising effect on the science of a country that goes far beyond their particular discipline. Even a geophysicist, for example, feels pride that the double helix was discovered in this country.

There is no doubt that science in the UK is depressed. This is the time to revitalise it. The argument that basic science should be left for better times is false. The country that now invests deeply in science, despite the state of the economy, will be the one that emerges from the present world recession ready to take the lead.

Furthermore, it's not just a question of money. If wealth creation is a matter of science (and its application through

engineering), science is a matter of scientists. And Britain has never had a coherent policy for the growth and encouragement of its scientific community—just the usual British compromise of a decision here, a regulation there, a patchwork but no policy. The research councils have done their best to regulate and redirect studentships and fellowships; but they can only tinker with the problem. There is an enormous—perhaps 5,000-strong—and vital community of bright researchers locked into a cycle of frustrating and demoralising short-term contracts, produced by the unwritten policy of using an excessive number of research students as cheap labour and the static university system blocked with middle-young tenured staff. Of course 'the best' always get jobs—that's only a matter of circular definition. The real question is of the wasted talent, the real talent, that does not find effective employment, either in the universities or in industry.

This problem is not Britain's alone. Even Germany suffers from it, despite its enlightened attitude to science. But the country that breaks through the logjam first will have an immense advantage. We challenge the new government to find effective, creative employment for Britain's post-doctoral fellows. A dozen new whizz-kid centres of advanced study, some applied, some pure? A proper career structure for non-teaching researchers at universities and medical schools would be a good start. The objective must be to create new research schools, either attached to universities as non-teaching institutes or completely independent. Research doesn't grow at random. It depends on potentially creative branches having the opportunity to develop at the right moment. The United States took its great lead in science when Europe rejected its intellectuals during the time of Hitler; they landed in America and research communities spread rapidly around them.

US pre-eminence in theoretical sub-nuclear physics, for example, can be traced largely back to Enrico Fermi's school in Chicago. And how did Britain invent its way through the second world war? It gave men like R. V. Jones responsibility the moment they could shoulder it.

We should take exactly the same attitude to our post-doctoral community. It must be given the opportunity to spawn its own schools of research, in an atmosphere where there is—if not total job security—at least hope, and growth, and vision. The age of this community—reaching into the mid thirties—is just right to bear fruit. (Studies by Harriet Zuckerman, recorded in her book *Scientific Elites* (Free Press, New York: 1977), show that the average age at which Nobel prize-winners did their prize-winning work was around 36. Those few who were under 30 were usually already members of flourishing research schools.)

So we say this to our new Prime Minister—whatever your successes or failures with industry and the more immediate problems of the nation: remember the scientists—and you will be remembered. □

# US academy denies threshold for radiation damage

A COMMITTEE of the US National Academy of Sciences, after many months of heated debate, last week confirmed its support for the hypothesis that ionising radiation has an effect on the human body that remains directly proportional to the dose even at very low levels, and that there is therefore no threshold below which such radiation can be ignored.

This decision has been reached by the academy's Committee in the Biological Effects of Ionising Radiation—(BEIR) which had been asked by the Environmental Protection Agency to reconsider estimates of the hazards of ionising radiation first made in a report published by the committee in 1972.

Pointing out the absence of clear scientific evidence on the shape of the dose-response curve for low levels of radiation—a source of much recent controversy over, for example, the hazards faced by workers in nuclear shipyards and power stations—the committee says that the linear dose-response relationship “emerges by default as the simple model whose use appears to be the least objectionable”.

This conclusion, however, and the estimates of increased cancer incidence to which it leads, is sharply contested by a number of committee members, who state in a minority report signed by five of the 22 members that “far too little theoretical information exists to serve as a reliable guide for extrapolation.”

Speaking at a press conference held by the NAS to present the report, Dr Harald H. Rossi of the Columbia University College of Physicians and Surgeons in New York, one of the minority group, said he feared that the report would “contribute to excessive, and potentially detrimental, apprehension over radiation hazards.”

In reply, Dr Edward Radford, of the University of Pittsburgh's Graduate School of Public Health, chairman both of the BEIR committee and of its somatic effects subcommittee, issued a public challenge to any member of the minority group, or any other individual, “to meet me in public debate to discuss these issues openly and to see who comes nearest to the truth.”

The committee was asked by the EPA to look at the available data on both the genetic and somatic effects of ionising radiation. With regard to the first of these, the committee says that it came broadly to the same conclusions as that reached in the earlier report, namely that one rem of parental exposure throughout the adult population would lead to an increase of between five and 75 additional genetic disorders (over a cur-

rent figure of about 100,000) per million live-born offspring.

“The first BEIR report used mice data exclusively to estimate the incidence of chromosomal aberrations. We have had a limited amount of human and monkey data that has since become available, and have come up with figures that are not significantly different,” said Dr Dean Parker, chairman of the genetic effects subcommittee.

By far the largest section of the report—a single chapter taking up over 500 of the report's 850 pages—is devoted to assessing the somatic effects of high- and low-LET (linear energy transfer) radiation, the first including radiation such as that emitted by alpha particles, the second by X-rays and gamma-rays.

The report says that over the past few years, new studies have modified some of the earlier views about radiation induced cancer in humans. For example, solid tumours—in particular breast, thyroid and lung cancer—were of greater significance than leukaemia in assessing the risks of whole body exposure, and partly as a result of this, it was now felt that the total cancer risk was greater for women than for men. In addition, there was increasing evidence that age is a major factor in cancer risk related to radiation exposure.

Addressing the effects of low levels of radiation—of the order of tens or hundreds of millirads—to which the general public might be exposed in addition to the natural background, the committee says that at present there is no way of telling whether this exposure is detrimental, and that in any case the somatic effects would be masked by environmental or other factors.

Given the lack of data, it says that “for most radiation-induced cancers, the possibility of a linear no-threshold dose-effect relationship cannot be excluded”, adding that, for low doses, the linear hypothesis is “consistent with plausible carcinogenic mechanisms at the level of the single cell.”

However, it points out that the linear hypothesis probably overestimates the risk from low-LET radiation (such as X-rays and gamma-rays), but may underestimate the effect at low levels of high-LET radiation, such as alpha-particles.

Referring to those who receive occupational exposure of between 0.5 and 5 rems a year, the latter now being the recommended maximum in the US, the committee says that “a discernible carcinogenic effect could be manifest” at these levels of exposure. (The average

whole-body dose rate to the 30,000 people currently working in the US nuclear industry is between 0.6 and 0.8 rems a year).

Applying the linear hypothesis to a variety of available data—in particular that obtained from survivors of the atomic bombs dropped on Nagasaki and Hiroshima—the committee estimates a lifetime excess of cancer incidence caused by low-LET radiation of between 192 and 756 cases per rad per million males receiving a single exposure, and between 344 and 1,031 cases for females exposed under the same conditions.

The number of excess fatal cancers was estimated as between 70 and 353 per million per rad per year for single exposure, and between 68 and 293 for continuous cumulative exposure. In comparison, a report published by the United Nations Scientific Committee on the Effect of Atomic Radiation in 1977 estimated an excess of fatal cancers of 100 per rad per million for both categories (the higher BEIR estimates are largely the result of assuming a cancer risk that increases with age).

The legitimacy of these figures is questioned, however, by a number of members of the somatic effects subcommittee. Following what are described as “unresolvable differences”, five have signed a minority report stating that the risk estimated given in the report for specific organs—many of which were derived from the Japanese studies—were excessive, and that these figures “might be used to justify radiation exposure but not to indict it.”

Dr Rossi claimed that there was much radiobiological and epidemiological data indicating that the linear hypothesis led to substantial overestimates of radiation risk. “There is therefore a danger in a report which includes any evidence of an increase when I feel that the risks are nowhere as high as those in the report”, he said.

Dr Radford agreed with Dr Rossi that the general alarm about radiation dangers associated with nuclear power were not entirely justified. “It is a risk, but it is not the end of the world by any means. People do things to themselves that carry a much greater chance of leading to cancer than the effects of nuclear facilities,” he said.

However, he defended the committee's decision to support the linear hypothesis for low level radiation, and argued that the issues raised about the interpretation of scarce scientific data were sufficiently important for the scientific community at large to become

involved in the debate. "Ionising radiation is a prototype of other environmental agents which may be carcinogenic, even at low levels, so a resolution of this matter is therefore important" he said.

In a separate study published earlier in the week, another NAS study group looking at the risks associated with

nuclear power concluded that according to evidence in the scientific literature, exposure from routine operations of the nuclear industry increased the cancer risk of the most-exposed members of the public by 0.1%.

If the nuclear industry was to expand along currently expected lines, there would be between 165 and 255

extra cancer deaths attributable to nuclear power operations up to the year 2000. The academy report says that production of an equivalent amount of electricity with coal-fired power stations would result in an estimated number of more than 3,000 associated deaths.

David Dickson

## Weapons laboratories 'should retain links with university'

AN advisory committee last week recommended to the US Energy Secretary, James Schlesinger, that the University of California should continue to manage two laboratories which carry out the bulk of US research into nuclear weapons. However, the committee says that the university needs to improve the effectiveness of the "trusteeship" it has for the two laboratories, the Lawrence Livermore Laboratory outside San Francisco and the Los Alamos Scientific Laboratory near Santa Fe, New Mexico.

The committee has also advised the department to make a close study of alternative ways of managing the laboratories—in particular it suggests a private, non-profit corporation—if opposition within the university to the current arrangement should grow to a point which makes it "undesirable or impossible for the university to continue the present relationship".

The university's links with the two laboratories, whose activities grew out of wartime research but recently expanded into energy and environmental research, has long been a source of controversy. Faculty and students have attacked the arrangement, some on the basis that the university's responsibility for classified research is unethical, others objecting more specifically to the weapons research.

The current arrangement under which the university manages the two laboratories for the Department of Energy comes up for review next year. Last December, Mr Schlesinger asked a working group of the Energy Research Advisory Board (ERAB) to review the current relationship and recommend how it should evolve "to best serve the needs of the nation and the laboratories". In its report, which was forwarded to Mr Schlesinger by the board last week, the working group says that the factors which have made the university beneficial to the country and the laboratories are "lasting and fundamental", and that the relationship should therefore be continued and improved, even though the university needed to discharge more fully its trusteeship. Referring to what it calls a small but vocal opposition to continued nuclear weapons R & D in any form, it says that protesters often complicate the laboratories' already

difficult public relations by instigating press coverage of "peripheral issues". "The laboratories need support in this area which the university could help provide" the working group says.

However it adds that more pressures may develop both within and outside the university, making it impossible for the university to continue the present relationship. "The DOE must be prepared for such possibilities, even though we believe them to be remote," the working group says.

The report generated controversy when it was discussed at a meeting of the full advisory board in Washington last Thursday. Mr Tom Cochran of the Natural Resources

Defense Council, said he felt the working group had not dealt fully with the criticisms that had been made of the current arrangements, and that it had narrowed its focus by discussing merely the university's ability and apparent willingness to manage the laboratories, ignoring broader issues.

After considerable debate, the board agreed by 13 votes to 4 to forward the working group's report to Secretary Schlesinger, with a covering note from the chairman, Dr Saul Buchsbaum, explaining why the working group had interpreted its brief in the way that it had. A minority report is being prepared by dissenting members.

David Dickson

## Anti-vivisection demo hits Cambridge

LAST weekend about three hundred people gathered in Cambridge—the place described by their leaders as the Mecca of biological research in the UK—to voice their disapproval of the use of animals in scientific experiments. For more than an hour they marched through the streets shouting their protests at empty laboratories and Saturday afternoon shoppers. They carried placards bearing slogans claiming "Cambridge scientists torture animals" and "your taxes pay for laboratory sadists to mutilate animals with no anaesthesia". The odd one called for the banning of the seal hunt and an end to factory farming.

The demonstration, which had attracted protestors from as far afield as Lancashire, Gloucestershire and London, was organised by Jean Pink of Animal Aid, an organisation concerned with the rights of animals, whose aim is to achieve the abolition of all animal experiments. "Vivisection is the ultimate in animal abuse", said Mrs Pink. "We demand the total abolition of the use of animals in laboratories".

The protest also included the delivery of a letter to the Vice-Chancellor of Cambridge University expressing the group's concern and a talk by Hans Ruesch from Switzerland, whose book *Slaughter of the Innocents* has recently been published. There is total ignorance about vivisection said Hans Ruesch. He claimed

that few know of the "complete and utter uselessness of medical research through experimentation". Movements to seek the abolition of animal experiments had recently started up in several countries, he said, in particular West Germany and Italy, and also Australia.

The meeting ended with a request that the new Home Secretary, Mr William Whitelaw, who has just taken up his appointment after the election of a Conservative government, should be bombarded with letters as soon as he gets to his new office.

Judy Redfearn

# Soviet 'mental illness' spreads to Czechoslovakia

Dr Snezhnevskii, of the Serbskii Institute of Forensic Psychiatry in Moscow, is well-known as the man who provided a theoretical basis for the practice of interning dissidents in mental hospitals. According to Dr Eva Dubska who left Czechoslovakia in 1977, at the time of her departure, Snezhnevskii's works were gaining support among certain sections of the Czechoslovak psychiatric establishment. A case history has now reached *Nature* which suggests that the Czechoslovak political establishment is prepared to add its weight to them.

According to Snezhnevskii, "all psychological illness is a form of schizophrenia. Further, he identifies a number of subtypes and symptoms not recognised abroad. These include "sluggish schizophrenia" (with no perceptible symptoms), "delusions of reformism", "a mania for protest" and the like. In the case of Augustin Navratil a 45-year-old Czech recently committed to the mental hospital in Kromeriz, there are disturbingly clear indications that the same diagnostic procedures have been used.

Navratil, who served as a local councillor for the revived People's Party under the Dubcek regime and who has since worked as a railway signal-box guard, was charged in January 1978 with slandering the state. (He had been collecting signatures for one of the many civil rights petitions which sprang up in the wake of the Charter-77 movement.)

After considerable bureaucratic delays, he was sent to the local mental

hospital for examination, and found unfit to stand trial; accordingly he was formally committed for treatment. The diagnosis includes such Snezhnevskii type expressions as "hysterical self-stylization towards the ideal of a strong leading personality and with a strong moral responsibility which the subject understands as 'fidelity to his principles' and an inability to adapt to an adequate view of social reality". Further "by analogy with the fate of past personalities the subject thinks that 'for the truth one must logically suffer'."

At times the report becomes near ludicrous, quoting IQ figures as evidence of an unbalanced personality, urging treatment although admitting that Navratil cannot be brought to change his views. However, it is suggested, it may be possible to make him conform at least outwardly.

It is, perhaps, this Kafka-esque cynicism which is the most alarming aspect of the case. Reading the report, one gains the impression of a trained scientist desperately trying to adduce some kind of substantiation for a diagnosis already determined. □

"I'm afraid, doctor prosecutor, you are suffering from hysterical self-stylisation as a psychologist with an inability to adapt to an adequate view of humanity"

## French stress scientific side of detente in space

Mr Brezhnev's invitation to France to supply a crew-member for a joint manned space-mission with the Soviet Union did not come as a complete surprise to the Centre Nationale d'Etudes Spatiales (CNES). Shortly before President Giscard d'Estaing left for his "official working visit" to the Soviet Union, the chairman of CNES, Professor Hubert Curien, said that CNES was considering the possibility of Franco-Soviet cooperation in materials-processing in conditions of weightlessness.

CNES welcomed Mr Brezhnev's proposal in principle. They are not, however, interested in France simply being another country to have one of its citizens in orbit. "We are a scientific group", a CNES spokesman told *Nature*. "Such cooperation could be quite interesting, but we want to know what programme or programmes would be involved. We have a lot of interesting programmes in hand, and if the cooperation comes to pass, it would probably be one of the people in charge of one of these programmes who would take part."

No date has yet been even tentatively set for such a mission, nor have any details been worked out. But if CNES stand by their wish that "he would be an experimenter rather than a pilot", a significant change in Soviet procedure would be involved. Since the

three crew members of Soyuz-11 died tragically during re-entry, Soviet cosmonauts have always worn space-suits aboard the Soyuz transport vessels. The extra bulk means that only two cosmonauts can be launched in one craft. Although one is officially designated the pilot, the other is trained to be able to take over the controls in an emergency. CNES, however, would appear to prefer their representative to be essentially a passenger, ferried up to an orbital station where he would then proceed with his experiments.

Although CNES, as scientists, deprecate the publicity value of participation in the Soviet space programme, both the French and the Soviet governments seem to place great stress on it as what Mr Brezhnev last week called a "barometer of detente". France has occupied the leading position among non-Comecon countries in bilateral space cooperation with the Soviet Union.

The first general cooperation programme to include space was signed in 1966, and was presumably intended by the Soviet Union to encourage de Gaulle in his attempts to detach France from the US and NATO. Although French foreign policy has changed under succeeding presidents, the general world climate of detente and the impetus which the Franco-Soviet

space programme had already built up ensured its fruitful continuation.

France has, accordingly, taken part in a number of joint projects with the Soviet Union, including a laser-reflector experiment to determine accurately the distance to the Moon, a study of the atmosphere of Venus, investigation of solar radiation from Mars probes, studies of the magnetosphere, solar neutrons and gamma rays, and a programme of simultaneous rocket launches to study the *Aurorae borealis* and *australis*.

At present, aboard Salyut-6, cosmonauts Vladimir Lyakhov and Valerii Ryumin are responsible for a France-Soviet materials-science experiment to synthesise magnetic alloys from materials which do not give rise to magnetic compounds in conditions of Earth gravity. This type of experiment will certainly be in the CNES planners' minds when they work out their programme for their "experimenter". Before he dons his space-suit, however, one important point remains to be settled by that branch of the Academie Francaise which regulates neologisms and loan-words. Is it the nationality of the crew-member or the registration of his craft which determines his designation? In other words, will he be officially described as an astronaut or a cosmonaut? □

**Carter urges expanded nuclear power programme:** President Carter has told members of the US Congress that he strongly supports an expanded nuclear power programme, and that despite his continued opposition to the liquid metal fast breeder reactor at Clinch River, Tennessee, he is still in favour of the development of a more advanced fast breeder. "I want to emphasise that my opposition to the CRFBR does not imply my opposition to breeder reactors in general or to nuclear power", the President wrote in a letter to Congressional leaders asking them to support his attempts to halt the Clinch River project. "We need to pursue a vigorous programme of breeder reactor research and development so that this option can be commercially available to us if and when we need it." The President's remarks became publicly known two days before a mass anti-nuclear demonstration was held in Washington.

**Official BNFL response on Windscale leak:** Sir John Hill, chairman of British Nuclear Fuels Ltd, has responded to government enquiries about the highly active Windscale leak first reported on 18 March. In a letter to Tony Benn, outgoing Energy Secretary, Hill outlined the history and current status of the leak. High activity of 200 millicuries per litre was first recorded from borehole number 63 in November after four previous samplings done earlier in the year showed a lower activity of 0.2 mCi/l. This lower activity "did not cause particular concern" says Sir John because it was consistent with contamination due to a spill occurring twenty-five years ago. By March, investigations showed that the new activity was consistent with activity discovered in an out-of-use steel-lined sump located in an annexe where buffer storage tanks are housed. The route from the sump to the borehole is still unknown, however. The letter states that laboratory tests show that the "mean" migration rates of  $^{137}\text{Cs}$  and  $^{90}\text{Sr}$  in soil are about 1 metre in "several hundred days" so that activity will have decayed "to an insignificant level before the site perimeter is reached".

**National Cancer Institute criticised over carcinogen testing:** The US National Cancer Institute in Bethesda, Maryland, has been strongly criticised by the General Accounting Office, the investigating arm of the US Congress, for deficiencies in the managements of its programmes for testing substances for possible carcinogenicity. In a report published last week, the GAO says that in particular the Institute failed to spot serious deficiencies in testing programmes carried out on a contract basis by private research companies. The GAO said that many of these companies used unacceptable procedures to test chemicals, and that many test results had had to be thrown out by the Institute, at a cost of millions of dollars. Another report published by the GAO has criticised the lack of sufficient training in professional ethics given to employees of the National Science Foundation, particularly over activities relating to dealings with possible future employers. The GAO says that in discussions with programme managers in the NSF, investigators found that it was not unusual to be asked for an interview with an organisation for future employment while involved in reviewing grant applications or monitoring ongoing work for that organisation.

**DHSS proposes increased job security for research staff:** Professor A. J. Buller, Chief Scientist at the UK Department of Health and Social Security, has proposed a new scheme to save the jobs of scientists faced with unit closures. Under the scheme participating directors of DHSS-supported units will consider researchers who are made

redundant by unit closures for any vacancies that arise—before they invite applications from other candidates. Directors of units are under no obligation to hire anyone they consider to be unsuitable. In addition the DHSS will make extra posts available to directors pending vacancies in their normal complements. The DHSS will also pay for researchers' removal costs. But researchers will be expected to move to any part of the country and if they refuse, "even if there is only one offer they will be made redundant". The proposal has been circulated to the 34 DHSS-supported units and will be put into operation when 20 units have accepted.

**Australian trade unions act to stop proliferation:** Mr Cliff Dolan, vice-president of the Australian Council of Trade Unions, announced last week that three major trade unions would withdraw their labour to halt two new uranium projects in northern Australia. Citing the dangers of proliferation, waste disposal and health hazards, the ACTU has opposed the mining and export of Australia's considerable uranium reserves estimated to be 20% of the Western world's supply. The Amalgamated Metal Workers and Shipwrights Union, the Australian Railways Union and the Electrical Trades Union have agreed at recent meetings to follow the ACTU's recommendation. The unions will stop manufacture of mine equipment and its transport to mining sites.

**Sweden and China to cooperate:** The Royal Swedish Academy of Sciences and China's Academia Sinica have signed an agreement on cooperation in basic sciences. The agreement, signed in Peking during a recent visit by Professor Carl Gustaf Bernard, secretary of the Swedish Academy, comes into force on 1 July and provides for mutual exchanges of scholars. The Swedish Academy of Engineering Sciences has signed a similar agreement with the Chinese. In a discussion of Chinese science policy, Vice-President Fang Yi told Bernard that he was trying to restore the damage done to basic science by the Gang of Four. Training scientists in the West was a good way of tackling the problem. Several hundred scientists will probably visit Sweden under the new agreement, beginning with ten interested in methodology in basic research. Another area in which the Chinese want Swedish help is geology. Developing their natural resources in one way of paying for their modernisation programme. In response to a question on environmental pollution, the Vice-President replied that in a period of enormous expansion, it was more important to build up the industries than to confine their pollution.

#### **India's new radio telescope operational soon:**

By the end of this year India's new aperture synthesis radio telescope will be fully operational. It is the latest addition to the Tata Institute of Fundamental Research's (TIFR) Radio Astronomy Centre at Ootacamund. Like the previous Ooty Steerable Radio Telescope, which was commissioned in 1970, its design and construction is completely Indian. Its resolution will be equivalent to that of a 4 km diameter parabolic dish. The new telescope is an assembly of seven antennae which will be linked to the main Ooty Steerable Radio Telescope. The total estimated cost of the additional antennae and associated equipment is 4 million rupees (£180,000), an amount which makes it one of the cheapest aperture-synthesis radio telescopes.

# Energy search comes down to earth

David Dickson reports on US hopes of extracting heat directly from the earth's crust

Hot dry rock, its supporters believe, offers one of the few practical, medium-term alternatives to fossil or nuclear sources of energy with little of the environmental problems or shortages associated with either. If it can be tapped efficiently, the potential energy available from the heat stored in the Earth's crust is enormous. It has been estimated that the energy supply for the US for a whole year is contained in a 50 cubic mile block of hot granite.

"We also think that it is the cleanest source of energy on the horizon," says Mr Greg Nunz, recently appointed manager of the Department of Energy's National Hot Dry Rock (HDR) Program at the Los Alamos Scientific Laboratory in northern New Mexico, where research into possible extraction techniques has been going on since the early 1970s.

At present, the most traditional and widely used method of extracting geothermal heat is through tapping underground reservoirs of hot water. The Los Alamos scientists, however, are developing ways of extracting heat from rock which is usually a result of radioactive decay, or of molten magma below the Earth's crust. The technique is to pump water down from the surface into a fracture that has been artificially created in impermeable rock. The water absorbs the heat from the rock, and is pumped back up to the surface again under sufficient pressure to prevent it from boiling.

"The concept is really very simple: we are literally trying to 'mine' the heat by creating a heat-exchanger underground", says Mr Nunz, pointing out that HDR techniques are therefore more flexible than those which require the existence of natural hydrothermal reservoirs.

Soon after discussions began at Los Alamos about the potential of HDR, field investigations were carried out into the high thermal gradient characteristics of the nearby Jemez Plateau, site of the third largest extinct volcano in the world. A preliminary test hole was drilled to a depth of 785 metres, where the temperature of the surrounding rock was found to be 100 °C. A second hole following two miles away at a site known as Fenton Hill. This found a temperature of 197 °C at a depth of 2,929 metres.

Steam is released at the hot dry rock facility, Los Alamos

The next stage was to pump water under pressure down the drill-hole, opening up plate-shaped cavities—the largest having a radius of 215 metres—at the bottom. A further hole was then drilled from the same site in the hope that it would intersect the largest cavity and provide a channel for hot water to be returned to the surface. Uncertainty about the exact shape of the cavity, however, meant that the new hole failed to make the intersection. Mr Nunz explains that "the instrumentation of the time was not up to the job".

The next two years were spent developing techniques to get a better understanding of the geometry of well-bores and of fractures. In early 1977, the first of the Fenton Hill holes was re-drilled, this time successfully intersecting a fracture made at the base of the second. And late in the year the first circulation of water took place, using a heat-exchanger at the surface to disperse the heat brought up.

Tests carried out so far on the completed system have been a "tremendous success", says Mr Nunz. For example, during an initial 20-hour run the temperature of the water reaching the surface rose by 130 °C. Water quality was good, with a low concentration of minerals that could have clogged up the system.

This was followed by a 75-day test at the beginning of last year, during which the amount of energy extracted rose to about 5000 kW. The amount of water lost to the surrounding rock stabilised at no more than 1.5% of the circulation rate.

The success of this trial system led the Department of Energy to announce last autumn that it was setting up a national Hot Dry Rock Geothermal Energy Program, to be managed by the Los Alamos Scientific Laboratory—itsself run by the University of California for the department—with the overall aim of determining the potential of HDR as a significant energy source, and if possible of providing a basis for its commercial development.

The scientists at Los Alamos are already convinced that energy produced in this way—at least that which

can be used for heating—is potentially competitive in price with other more conventional sources of energy, and is likely to become increasingly attractive as the price of the other sources continues to rise. A recent study carried out with economists from the University of New Mexico, for example, reached the conclusion that in areas where the geothermal gradient is 40 °C or more per kilometre depth, electricity produced by HDR techniques would be competitive with other sources producing energy at 3 cents a kilowatt-hour.

The scientists also claim, that, so far, they have not been able to detect a significant environmental impact from the work on the Fenton Hill site. There has been virtually no disruption of local ecosystems, neither has the drilling caused any measurable seismic activity.

The next step in the national programme is to see if the results achieved at Los Alamos can be repeated elsewhere. Already three of the 100-mile square sites in different parts of the US are being examined as possible candidates for a second drilling programme. Meanwhile back at Fenton Hill, work has already started on a deeper hole, drilling to temperatures around 260 °C, which, it is hoped, will be able to demonstrate the commercial potential of HDR to interested utility companies. If successful, this could lead to a 50 kW experimental plant, sufficient to provide the electricity needs of 5,000 people.

One problem that the programme managers face, however, is gaining public recognition of the potential of HDR. "Right now, public perception of the potential is almost zero. And we are planning to have a contractor look at the problem and decide the most cost-effective way to do some public education," says Mr Nunz.

Among those to whom the message will be directed are likely to be members of Congress. So far federal support for the HDR programme has been extremely modest compared to the amount spent on research on other energy sources. Funds for the first few years' research came from the Laboratory's discretionary money, and

over a seven-year period the whole programme has cost under \$40 million.

Already other countries, particularly those with favourably geological conditions, have shown close interest in the programme. Once a year the programme managers hold a formal seminar in Sante Fe to discuss the progress of the project, attended by scien-

tists from many parts of the world. Both the Japanese and West German governments have offered to provide funding for the programme.

The federal programme is now focused on 1986, when a decision will be taken on whether to move the whole programme up to a near commercial scale.

At Los Alamos, they are confident that these investigations will be successful. "I don't think that the world has discovered hot dry rocks yet. But we see it as the only major alternate energy source that can be developed in this century, and do not understand why the powers that be are not more excited about it," says Mr Nunz. □

## Harrisburg shakes up Sweden's nuclear war of words

THE Harrisburg reactor accident hit the Swedish nuclear energy debate like a karate chop. The Social Democrats, long supporters of Sweden's nuclear development and opposed to a referendum on it, announced that the accident was serious enough to make them change their basic judgements: there should be a Swedish committee of enquiry into Harrisburg and a referendum should be held. The Liberal party government changed with them and declared that no more reactors should be loaded until after the referendum. And an opinion poll taken after the accident shows a dramatic anti-nuclear swing: 53% of people asked said that they would vote against nuclear power in a referendum and only 26% said they would vote for. In January, the same question produced 43% against and 41% for. On the face of it, then, Sweden's nuclear future is wide open again. Or is it?

The seven years of Sweden's public nuclear debate has shown that facts enter politics only to the degree convenient for either side. More facts are being gathered now: a party of Swedes and Danes left this week for Harrisburg, and, on the domestic front, a working group is about to investigate Good Friday's accident at the Barsebäck 1 plant, within sight of Copenhagen. In this accident—"the worst in Sweden so far", according to a spokesman at the Nuclear Power Inspectorate—the generator exploded, throwing out metal projectiles (including a two-ton steel capsule) which did not, however, penetrate into the reactor itself. But it is hardly likely that any of the facts uncovered by these groups will be treated any differently from those already paraded. The referendum, to be held next spring, will be advisory—but its 'advice' will no doubt be used only so far as the politicians find convenient.

The last act of last year's three-party coalition government was to refuse the nuclear industry's application for the loading of the Ringhals 3 and Forsmark 1 reactors, on the grounds that the industry had not shown the existence of a sufficiently large rock formation with appropriate characteristics for final disposal of waste. The government said that, if the industry found rock they

considered more suitable, and if it is approved by the Nuclear Power Inspectorate, the government would give permission to load the reactors. After the coalition fell, and the pro-nuclear Liberal party government took over, the industry duly made more inspections on Sternö, near Karlshamn in southern Sweden, and made a new application.

The Inspectorate decided to appoint a group of eight independent geologists (six from Sweden, the others from Norway and Finland) to assess the industry's report, giving the Inspectorate's Board a factual base for its recommendation to the government. The new government announced that it would be bound by the Inspectorate's recommendation—and that it was confident that the Inspectorate would be able to recommend that the loading should go ahead.

### Rock unsuitable

Seven of the eight geologists found that the geological properties of the Sternö rock were such that it "cannot be used for the storage proposed by the nuclear industry". They reported: "The holes drilled (by the industry) are too few and drilled in such directions that, even if they had all shown fracture-free, homogenous rock, they would not have sufficed to show unambiguously that the rock fulfils the set conditions." The group found fractures not discovered by the industry, and these could reduce the area usable for storage from the desired 1 km<sup>2</sup> to 0.3 km<sup>2</sup>. Although storage requires homogenous rock, the investigated area contained three different types of rock, and the consequences of this had not been sufficiently investigated. The group maintained that it is impossible, at present, to determine the permeability of the rock—yet the nuclear industry's safety analysis depends on this parameter.

But the Inspectorate's Board did not recommend that the loading be stopped. In a masterly formulation, it told the government that the geological qualities of the rock must be seen in the context of *all* the barriers designed to prevent leakage of waste including vitrification and encapsulation. "The

Inspectorate does not maintain that each one of these barriers must give that degree of protection assumed by the nuclear industry in order for the final result to be regarded as wholly secure. . . . The importance of the demands made on the geological barrier should not be exaggerated . . . if the other barriers work satisfactorily." The question of whether the industry had shown that the rock met geological standards for deposition of nuclear waste was neatly sidestepped. The Board said that it was not unanimous on the meaning of the word "show", and therefore could not say whether the standards had been met or not.

"This has been such a political affair that science has been totally overridden", says Dr Arne Wesslén, one of the eight geologists. "It is regrettable that a regulatory authority can appoint a group of experts who give such a consistent opinion, and then ignore it for political reasons." Dr Bengt Åberg, another of the geologists, agrees. "We did the work scientifically. The Inspectorate tried to find ways around certain parts of our report", he says. And a spokesman at the Inspectorate admits, "We found ourselves under intense political pressure".

Ironically, all the geologists think that it should be possible to find rock in Sweden with the desired characteristics. "Sternö was not chosen for geological reasons", says Dr Åberg. "The industry has had to rely on areas it owned or where it was given permission to drill. On Sternö, no holes could be drilled outside the power station fence! We should have a law allowing drilling to be done in geologically-likely areas."

The day after the Inspectorate's Board met, the accident happened at Harrisburg. In the aftermath of that, with the ban on loading more reactors until after the referendum, the Board's verbal acrobatics proved to have been unnecessary—for the time being. Politicians' energies are now concentrated on the fight over the wording of the referendum question, and bitter fights lie ahead. In the meantime, as September's general election looms, nuclear power is not likely to be forgotten.

Wendy Barnaby

**UNCSTD '79:** This is the first of a series of articles leading up to the opening of the United Nations Conference on Science and Technology for Development (UNCSTD) in Vienna on 20 August. So much hot air has risen over the nature of the conference itself that the real problems facing science and science planning in the Third World have been forgotten. So we sent a team of writers to the grass roots. We asked Dr Hanlon

to look at the problems, on the ground, of an African country. He chose Ghana. We asked Anil Agarwal, a respected Indian science journalist now working in London, to visit India to report on the changing shape of science under the Janata government. And we have granted writing fellowships to scientists to visit and report on affairs in South America. We shall also have reports on South-East Asia and the Middle East.

## Ghana: struggling for scientific independence

"TWELVE years ago I came back with a PhD in magnetohydrodynamics. I tried to work here, but there was no point. It was totally useless in Ghana." Now K. O. Kessey is professor of mechanical engineering at the University of Science and Technology (UST), working in refrigeration. "Twelve years ago, I couldn't imagine me doing earthly things—I was highly mathematically inclined. But you must use your knowledge and experience in a new situation. Students come back from abroad and they are helpless and hopeless. They say 'Oh, I don't have the equipment to continue my work'. So they do nothing. But it's just an excuse."

Dr Dwuma-Badu, head of the UST pharmaceutical chemistry department, and one of many working on herbal medicine, said: "With the equipment here, we cannot challenge pharmacy schools in developed countries with synthesising new compounds. So we work with Mother Nature to find what is there."

These comments reflect a growing change in Ghana. Science there used to be closely modelled on the British pattern; but as more graduates returned from studying abroad they began to question the relevance of their training—and of Western science in general. Meanwhile, the government, which had previously ignored science, began to ask what it was getting for its money. Both sides began to realise that Western science had simply been transplanted and allowed to grow in isolation, producing neither good science nor anything useful for the country.

As a result, the government set up a committee to review the Council for Scientific and Industrial Research (CSIR), and after its highly critical report, CSIR sharply changed direction. The Five Year Plan published two years ago was also the first Ghanaian development plan to have a section on science and technology.

As Dr M. N. B. Ayiku, head of CSIR's Industrial Research Institute explains, "there is only one science—only one set of laws of nature. But in a particular society, a certain type of science is emphasised. There is bound to be an accent based on our own problems. We must start small and

First World universities still set the pace for science in Africa. But the resulting research is often irrelevant

### Report by Joseph Hanlon

solve the little problems first. But as you solve the little ones, you unearth the big ones." And that brings new areas of basic science into view.

Professor Albert N. Tackie, head of CSIR, points to the other side: no one else will solve Ghana's problems—such as malaria. "If we want to tackle our diseases, we will have to do the research." Similarly, he points to building, where Ghana still relies on imported cement when it should be concentrating on local bricks and timber. The latter requires the study of another problem that is much less serious in temperate zones and thus little researched—termites and other insect pests.

Basic research—now underway on several Ghanaian problems, may have application elsewhere, for example:

- At UST, the chemistry and biology departments are working on bacteria to leach gold ore from the sulphur in which it is embedded.
- At the University of Ghana geologists are studying an earthquake fault which runs through Accra. It has not been active until recently, and its activity is not explained by current theories, so it is of general geological interest. The research also has practical value for Accra, where 16 people were killed in the 1939 earthquake.
- The Food Research Institute is looking into the preservation of kenky, fermenting corn meal, which must be sold and eaten in just a few days before it becomes too sour. The Institute is experimenting with dehydration to improve storage and distribution. Little work has been done elsewhere on drying fermented doughs, because they are rarely eaten in developed countries.
- Ghana is well-advanced in the study of herbal medicines (the subject of a later article).

Not all of Ghana's scientists have made the transition; it has been hard even for those who support the changed policy. J. Maud Kordylas, head of the Food Research Institute,

talked of her own research. She is now working on the use of the winged bean as a weaning food. Nutrition studies have shown a definite need for a supplemental weaning food, but peasants cannot afford to buy commercial ones. The winged bean can be grown locally and is an important source of the amino acid methionine. Kordylas's work on processing the bean is very different from what she was doing before. "I worked on vitamin A metabolism with respect to cholesterol at the London School of Hygiene and Tropical Medicine. I see high blood pressure in Ghanaians and I know they eat a lot of palm oil which is high in vitamin A, so I know it would be useful. And that sort of work gives me more satisfaction as a person. But we have many nutritional problems. In practice, the winged bean is a more useful project for Ghana."

Postgraduate studies abroad remain a necessity, but Ghana now scrutinizes these more closely. CSIR sends many of its research officers abroad for MScs and PhDs, and four years ago, it began vetting their research projects to make sure they are relevant, according to Tackie. Nicholas Darkwa, for example, has recently returned from North Carolina University with a PhD in pulp and paper science. His research topic was making paper from the stalks of plantain, a banana-like plant very common in West Africa, and CSIR actually shipped plantain stalks to him in the US for his work. Another CSIR researcher is studying making paper from local hardwood trees as part of his work in the USSR. Tackie hopes that the two will form the scientific basis of a Ghanaian paper industry.

The other side of education abroad is the brain drain, both short and long term. Foreign countries may subsidise Third World students, but they extract a high price—encouraging the brightest to remain abroad. UST vice-chancellor E. Bamfo Kwakye comments "to send your best students out means that you neglect your own postgraduate activities. Furthermore, it costs 24,000 cedis a year to keep a postgraduate student in the US—we pay a professor less than half that. Finally, we have severe staff shortages." So UST has changed its policy: fewer students are sent abroad, and an effort is being

made for joint MSc programmes, in which the student returns to UST to finish his or her research.

Although the new policies of UST, CSIR, and others are working well in some areas, in others they are not. UST has a joint chemistry MSc programme with a foreign university which simply allowed UST students to enrol there for a PhD rather than return to Ghana, defeating the whole point of the programme. A physicist told me he was working on electron transport in thin manganese films, a project of no apparent relevance to Ghana, because it was the area of a visiting British professor. Manganese may not be useful for Ghana, "but for someone who wants to get his PhD and get promoted, it is useful," commented the physicist honestly. Promotion is always a bugbear in science, and it is a special problem in Ghana, both because the system is very rigid and because it has failed to take into account the new attitudes toward research. "People are employed on the basis of being world class scientists who are employable in Britain or the US, not on whether they can solve local problems," declared M. D. Swain, a Ghana University botanist.

Promotion at CSIR, for example, is based on four things: a list of publica-

tions, reports on those publications by outside assessors who are primarily foreign, annual assessments, and supervisor's comments. There is little consideration of work that may have been highly useful but has not led to publications. Ayiku complained: "If I want promotion in CSIR, my *curriculum vitae* is sent to Germany or England, where I am judged by European standards." CSIR claims to have changed its policy somewhat, using a few local assessors for papers, for example. But few people, inside or outside CSIR, seem aware of the change.

In practice, the universities are just as bad. "It shouldn't be the *sine qua non* for promotion to be published in prestige Western journals," admits Kwakye—but it still is.

Often, because of rigidity, places simply do not get filled. Several UST departments do not have professors, even though they are being run perfectly well by acting heads who only lack the paper qualifications. One University of Ghana department has four of its 11 senior positions vacant. Yet, when a highly competent man applied, he was rejected—because he had failed his first year of university, even though he repeated it successfully and has since done well.

There are few local journals and they are rarely published because of lack of foreign exchange, so publication means publication in a foreign journal. One botanist considered looking at sour grass, a weed first noticed in Africa only two years ago and now slowly spreading out from Accra. It would have made a useful piece of scientific work, ideal for a local journal; but lacking international interest, it would not qualify for a foreign journal. So the work was not done.

Another adverse factor is the lack of an outlet for the results of relevant research. Scientists complain that, despite the lip service paid in the Five Year Plan, research is still not taken seriously. Ghana's national paper for UNCTSD, written by Tackie, complains that "the major scientific and technological institutions such as CSIR and the National Standards Board are not involved in investment decisions . . . development planning is entrusted almost exclusively to economists. . . . There is no effective accompanying technological evaluation."

There is little industrial take up of ideas generated by researchers, either. UST set up a few small manufacturing units on campus using simple equipment and local materials. The engineering faculty makes pumps and traffic lights and the arts faculty has a ceramics production unit. "Originally, we hoped that entrepreneurs would take these out of our hands, but this has not happened, so we continue to manu-

facture," Kwakye said.

Continued dominance of the economy by foreign companies also reduces the opportunity for local researchers. "The multinationals are so powerful; Ghana is so poor. It is impossible to think how we shall break this hold," comments Kwakye. Much applied and basic research is done outside the country or by outsiders. For example, when off-shore oil explorations began, the international oil companies asked local geologists to give them a basic briefing, and then they brought in their own geologists. So the local geologists gained nothing out of the project except a few small fees.

The scientists themselves are partly to blame. The ecology and geology of Ghana remain poorly studied. Tropical forests are Ghana's second highest foreign exchange earner, yet they are little researched. Tropical ecology is different and much more complex than temperate, and is sure to become a prime research area as the temperate zones are better understood—indeed, much basic science in the future will probably have a tropical bias. But it is not the Ghanaians who are moving into these new areas, but the white expatriots and visitors. Even the research into earthquakes is dominated by people and equipment from London University.

Some change does seem to be taking place in Ghana, however. There has been a realisation, as the UNCTSD paper notes, that "some of the measures taken so far towards the goal of economic independence have paradoxically led to a greater degree of dependence on the industrialised nations." Ayiku notes that Ghana has been buying technology as if it were Coca Cola—to be consumed and thrown away with no understanding of it. As Ghana University geologist Mike Mensah points out: "a developing country that cannot do research will always be an importer of technology."

But, as the UNCTSD report also notes: "The Ghanaian experience suggests that mere growth in the volume of scientific research or the use of advanced sophisticated industrial plants or machinery will not of themselves bring about development. It is essential that scientific research should reflect the true needs of development."

This must be done with the facilities available in Ghana. Ivan Addae-Mensah, a University of Ghana chemist, concludes: "If you want to do high-falutin sophisticated research, you can't get anything done here. But if you actually want to be a scientist here, you must look for the problems around you." □

# Why eating should carry a government health warning

It is time for scientists to swallow their doubts and press for a proper food policy which will save lives, say **John Rivers** and **Philip Payne** of the Department of Human Nutrition, London School of Hygiene and Tropical Medicine

It is generally agreed that food can kill, but argument persists as to whether anything should be done about it. Government action on diet and health has so far been minimal essentially because argument over the exact risks of eating has dwarfed any attempt at exploring the problems of doing something about them. We believe, however, that the latter issue is not merely as important as the former, but must be resolved first: we must know what kinds of action we might conceivably agree to before it is even worth considering the role of diet in disease.

It is widely agreed, by both nutritionists and the general public, that changes in diet occurring in the past 100 years have at least some role in the increased incidence of a whole range of diseases from dental caries and obesity to cardiovascular disease and cancer. These dietary changes have been many and complex, and major controversies exist as to exactly which are to be held responsible for the increase in diseases of affluence.

Considerable publicity has been given to such controversies, not least by interested organisations in the food industry who feel their own products might be under attack. Understandably such publicity as a rule is aimed at defending the notion that all existing consumption patterns are expressions of free choice, and should be regarded as innocent until proved guilty. This philosophy of waiting for absolute scientific proof attracts much support from the health professions, not least because it implies both the need for much continuing scientific research, and that the professions involved will define and apply their own criteria for what constitutes adequate proof.

Paradoxically the adherence of the health professions to a philosophy of waiting for certainty coexists with a broad professional consensus that would support moderation in eating, a reduction in fat and sugar intakes, and, in consonance with many other fashionable theories about conservation and ecological balance, some degree of reversion to diets with greater proportions of plant foods and fewer refined components. This consensus is clearly only provisional. That is, whilst there is not wide agreement that these changes will ultimately be shown as

sufficient, or indeed necessary to bring about a general improvement in nutrition, they are currently widely accepted as reasonable goals for any individual interested in conserving health. It is, in short, the best advice we can offer at present.

Unfortunately the nutrition profession in the UK has a somewhat vacillating attitude about what to do with its consensual knowledge. There is much pride about the role that nutritionists apparently played in the institution of a nutritionally based food policy during the second world war. There is widespread involvement with organisations like FAO and WHO in attempts to ensure that nutrition is integrated into the development policies of the Third World.

Yet concern for the nutritional problems of our affluent society is not translated into such decisive action. Admittedly individual nutritionists try to persuade, cajole and educate the public, but the profession has, as yet, stopped short of concerted action. It does so on the ground that present knowledge is inadequate. Clearly it is, but insofar as dietary moderation would tend to halt some of the major current trends of dietary change, it represents a policy of conservative caution, an attempt to stand still until the implications of change are better understood. This is a powerful argument to weigh against the elusive ideal of certainty.

It is generally agreed that piecemeal nutrition education usually fails, and some government action is needed. If the government were persuaded to support a strategy for health it would require at least consistent and relevant action by various ministries, and possibly regulations for the control of advertising. Such a sweeping approach might well be effective in changing the overall pattern of consumption, but is resisted on two grounds: it would constitute an unjustified interference with free choice; and the economic costs to agriculture and industry of adapting to new patterns of demand would be unjustifiable in view of the uncertain benefits. We reject both these objections.

In the UK, government intervenes in agriculture in many different ways, and any idea that we have a free market economy in food is a myth. The choice

*Choosing can be difficult . . .*

is between agricultural policies that ignore the health of the consumer, and those in which health is one of the considerations used to frame policy. At the moment, health enters only peripherally into, for example, regulations to prevent the adulteration of milk. The central complex of subsidies and support systems that shape agricultural policy in the UK seem to exist for wholly non-nutritional reasons. The subsidy on butter may make political sense, but, in a country where the consensus advice is to reduce dairy fat consumption, does it make nutritional sense?

The incentives for producing fat animals result in masses of fatty carcass waste that is used in the manufacture of cheap convenience foods such as sausages and beefburgers. A health conscious consumer has a difficult balance between cost, time and risk to cope with, and he may feel that choosing a diet he regards as unhealthy is an unavoidable risk. The refusal of the Milk Marketing Board to make reduced fat milks freely available; the absence of regulations requiring the labelling of cheeses with fat value; the widespread use of sugar in processed foods; the high price of wholemeal bread—all these results of government food and agricultural policies, or the marketing practices of virtually uncontrolled oligopolies, seriously impede any individual seeking to follow the sort of dietary advice which most nutritionists, doctors and the UK Department of Health and Social Security offer.

The existence of non-nutritional agricultural policies makes nonsense of the argument that inaction on diet and health should persist until final proof is

... especially when agricultural policies favour convenience foods

obtained. There is no doubt that the current nutritional debate is tentative and incomplete, but if nutritional factors are to be used with political and economic ones to frame agricultural policies, all that need be asked is that the predictions in each area should be equally plausible. To accept political intuition about the benefits of an agricultural policy while making a philosophically impossible absolute proof the criterion for scientific inputs is to emasculate scientific advice to government.

We believe that the health professions should unite in urging now a cautious and conservative basis for a nutritionally oriented food policy. Once they do so, however, there are other challenges to be faced, and it is important to pursue further some of the possibilities which expanding scientific knowledge will raise. It is reasonable to expect a hardening of the consensus view about the adverse health effects of some particular food or nutrient, and questions will then inevitably arise about further legislation, more specific advice or more rigorous action. If we consider now what kinds of scientific evidence would be needed to justify such intervention, nutrition research could be planned so as to contribute most effectively to the social and political processes of policy choice, and hence to health.

Clearly the risks of consumption of a given dietary component vary with the amount consumed. Since there is a wide variation between individuals in the amount of any dietary component that they consume, there will be wide variation in the risk to which they are

exposed. This will be increased further by variations between individuals in their constitutional sensitivity to disease. The benefits derived from a given 'across the board' reduction in intake will also, therefore, be highly variable.

If food and agricultural policies designed to combat disease are to be both effective and equitable it is necessary to define both the intake-risk relationship, and the acceptable level of risk in quantitative terms before it is possible to consider precise costs and benefits of the policy options open. The problem of what constitutes an acceptable level of risk is encountered in legislating against all sorts of hazards and the defining of acceptable levels is not a scientific problem, but a social and political one. However, the problem of intake-risk relationships does require scientific definition, since their nature can drastically modify the health policy chosen.

If the intake-risk function is linear (curve A in the diagram), everyone with an intake above  $I_A$  is above the acceptable level of risk, and in the example this constitutes the majority

of the population. If however the asymptotic function, curve B, applies only the small fraction of the population consuming more than  $I_B$  is at risk.

Clearly the difference in size of these risk groups means there will be great differences in the effectiveness of nutrition policies aimed at the whole population. Moreover, since measures to reduce disease will, in general, impose on those not at risk, the political implications, and the long term acceptability, of such policies will also differ markedly.

If nutrition theories are to be translated into nutrition policy, the quantification of the currently accepted relationships between risk factors and disease is more important than simply trying to increase our certainty about the strength of that relationship.

A change in the direction of nutritional research from causality to risk is a major one, and many scientists may view it with suspicion. But since in the foreseeable future nutritional knowledge will be chiefly applied through social policy, it is a change that must occur.

One further change seems probable. At present where nutrition policies exist at all, they have been evolved by senior administrators in closed counsel with leaders of the health professions. Such cabals will not survive for long. Misgiving about the role of scientists in government have grown to a general lack of confidence about "establishment science" as the debates over the Dangerous Pathogens Advisory Group or Windscale have made clear. It seems likely that general public concern about the role of nutrition in disease, will soon be matched by public demands to be involved in framing the policies necessary for change.

Such a change will underscore the irrelevance of the nutritionists' professional standards of certainty. Indeed they will strip away much of the veneer of professionalism that the subject has acquired. But once nutritionists recognise the essentially political nature of decisions about food policy, and the necessarily tentative nature of the theories that underpin them, we believe that they will welcome the involvement of consumer organisations and other pressure groups in the consultative process. It is reasonable that they should. At present while some scientific advisers strive after absolute proof in their decision making, the food industry employs others as spokesmen in the scientific debate, exerts massive influence on the direction of research by the funds it deploys, and by advertising pressures continues to manipulate food habits in ways that are widely suspected as having led to increased disease. A change in the way we tackle these problems is long overdue. □

## Select Committee's future

SIR,—In its recent First Report (17 July, 1978) the Select Committee on Procedure proposed some important and far-reaching changes in the procedure of the UK House of Commons. These include the establishment of a separate select committee for each of the departments of government, or groups of departments.

Our concern in this letter is with only one of the proposals, namely the dissolution of the Select Committee on Science and Technology whose work, it is said (paragraph 5.40), "should in future be carried out by the departmentally-related committees . . ." This proposal is supported in the report by an argument to the effect that the proposed new committees "would in no way be inhibited from taking evidence from any government department or other body relevant to the studies which they undertake."

Nevertheless, it is the view of the Executive Committee of this council that such a decision would be a retrograde development. We strongly support the opinion expressed to the Select Committee on Procedure by Mr Arthur Palmer MP, the Chairman of the Select Committee on Science and Technology, as indicated in paragraph 5.40 of the First Report. Departmental committees, said Mr Palmer, could not "adequately meet the need for parliamentary scrutiny of scientific and technological developments" since "inter-departmental subjects, however important they might be, would be accorded a lower priority".

The Committee on Procedure's argument depends on the generality of the policy of spreading science research and development amongst the departments of government. From many points of view there are good reasons for continuing this policy, where "after brief experiments in the 1960s with co-ordinating ministries, governments of all complexions have decided to leave scientific and technical research in the hands of individual ministries with only vestigial co-ordinating functions remaining at the centre" (paragraph 5.19). It does not follow from this, however, that the *scrutiny* of these activities should be compartmentalised to the same degree. Indeed, it is precisely because the central coordinating functions for scientific and technical research are vestigial that the work of the Select Committee on Science and Technology is so valuable.

Presumably, within the proposed system, there would be parliamentary committees for each of the Departments of Education and Science, Energy, Environment, and Industry, and perhaps other departments as well, all dealing with particular aspects of science and technology. Such committees would, undoubtedly, serve a valuable purpose in scrutinising the day-to-day, ongoing, short-term, research that is central to the work of each department. But no amount of "liaison and cooperation" between such committees "to allow joint inquiries and consultation, where committees share an interest" (paragraph 5.20), could deal satisfactorily with the broader, long-term, issues of

science and technology.

This can be seen at once from the issues that have already been taken up by the Select Committee on Science and Technology. These were necessarily concerned with scientific and technological questions drawn from a whole range of departments such as energy, environment, industry, health and social security, etc. Current issues of great political, social and economic significance, such as the potential benefits and hazards of genetic manipulation or the future effects of electronic microprocessors, obviously overflow all the boundaries appropriate for the administration of science and research within the government machine. By its terms of reference, which encourage it to scrutinise positively the activities of the executive on such issues right across the board, the Select Committee on Science and Technology fulfils an indispensable role on behalf of the lay public which its members are elected to represent. From the experience of our council and the detailed studies that we have made of policies and procedures relating to the social and political context of science and technology, it is clear that this is a role that should be considerably strengthened, rather than weakened, as proposed. As an institution endowed with all the constitutional authority of Parliament, capable of mediating effectively between the various domains of scientific expertise, governmental administration, and the concerns of the general public, the Select Committee on Science and Technology is potentially one of the most valuable social instruments available to us in times of rapid and bewildering technical change.

In the past the Select Committee on Science and Technology has not always been able to achieve this full potential. From our own close contact with members of that committee, and from our observation of its work, this is not due to any fundamental defect in its terms of reference, but rather to the very limited permanent staff resources, and restrictions on the appointment of specialist advisors, under which the committee has laboured. These deficiencies are recognised in the First Report from the Select Committee on Procedure, which recommends much improved arrangements in this respect. In our view, it is ironical that these resources should now be made available to new select committees which are to be much more closely linked to particular departments where technical staff resources abound, whilst proposing to terminate a committee which has been weakened by lack of such resources.

In our view, the proposed new system would perpetuate, in a most unsatisfactory manner, the split between science and technology which occurred when the DES was first created. Furthermore, there are many areas within technology itself which cannot be neatly divided into the interests of Departments of Energy, of the Environment, of Industry, etc. This fragmentation is not merely inconsistent with the realities of modern scientific research and technological innovation. It also takes a narrowly instrumental view of the contributions of various expert

disciplines to the issues raised by technical change. It is not so much, as the report suggests (paragraph 5.42), "that scientific and technical matters in widely varying fields involve a common approach which can best be handled by common methods"; it is rather that many current issues and policies cannot be adequately scrutinised except from a point of view that transcends and integrates the separate departments of government. The various proposed departmental committees, however loose their terms of reference and however well "coordinated" they might be over particular issues, could not adopt a sufficiently comprehensive viewpoint where social, environmental, economic, health and safety and industrial factors would be related to narrower technical or administrative matters.

We hope, therefore that Parliament will consider very carefully before dissolving the Select Committee on Science and Technology. Whether or not departmental committees are created, we believe that the Select Committee on Science and Technology should be retained. Its broad remit it seems to us, is just what is needed for the purpose of taking an overview of the various areas where pure science interacts with all the separate branches of technology, and where these branches interact with each other and where they may also have far-reaching social consequences.

## Scientist-entrepreneurs

SIR,—One aspect was not mentioned in the article by Dickson (5 April, page 494) concerning the commercial payoffs of recombinant DNA research. It is clear from the article that one of the 'fall-outs' of recombinant DNA research is the emergence of a group of scientist-entrepreneurs. Practically all the research which has led to the discovery and techniques of recombinant DNA was funded by public monies. It is obvious from the article that the recipients of these grants have jumped in with both feet in aiding to set up commercial companies to capitalise on the possible future profits resulting from the large-scale exploitation of recombinant DNA techniques. One wonders who will gain the monetary profits—only the stockholders of the companies or the scientist-entrepreneurs as well. One also wonders at the disinterestedness of the scientists, who clamoured for no restrictions on the research, giving as a reason the possible great public health benefits which might result. It seems clear now that if the benefits materialise they will accrue not only to the public, but also to the companies and the scientists. It seems to me that there is an ethical issue in all this, for while in our capitalistic society companies are supposed to make money, in our scientific society scientists are supposed to search for 'the truth', for the benefit of all and are not supposed to make money from their research, particularly if it was funded by public monies.

## Unsuspected relatives of the ovalbumin gene

from Norman Carey

THE power of cloning techniques in the analysis of the eukaryotic genome is once again dramatically demonstrated by a paper published in this issue of *Nature* (page 125). Using the new methodology, genes apparently related to, and lying close to, the ovalbumin gene have been discovered. It seems unlikely that any other procedures would have uncovered their existence. This paper, whilst revealing yet further complexities in the organisation of the eukaryotic genome, could also lead to studies in which the control of gene expression by steroid hormones can be elucidated.

The abundant capability of the avian oviduct for protein synthesis which is under the control of steroid hormones, has lured a number of major groups to study this tissue in the hope of discovering the basis of at least one mechanism of control of protein synthesis. The early phases of this work (reviewed for example by Palmiter *Cell* **4**, 189; 1975 and O'Malley & Means *Science* **182**, 610; 1974) established that oestradiol, with or without other hormones, stimulates the growth of the tissue and the synthesis of the four major egg white proteins, ovalbumin, conalbumin, ovomucoid and lysozyme, which together can account for over 80% of the protein synthetic capacity of the cell (Palacios *et al. J. biol. Chem.* **247**, 2316; 1972). It has also been shown that the presence of the hormones promotes the accumulation of the messengers for these proteins, and if the hormones are withdrawn, the messenger content of the tissue declines to very low levels. This, and similar observations, has led to the proposition that oestrogens induce the synthesis of the proteins by a process which is the eukaryotic equivalent of the Jacob-Monod hypothesis of operon induction, a contention which has proved very difficult to support. The three effective steroids, oestradiol, progesterone and testosterone, affect the synthesis of the

major protein components differentially, in such a way that the induction process seems likely to be very complex. The experiments designed to test the proposal have been open to more than one interpretation and, in addition, other effects of steroids have been observed, such as the ability to stabilise mRNA (Palmiter & Carey *Proc. natn. Acad. Sci. U.S.A.* **71**, 2357; 1974).

This phase of primarily kinetic studies drew to a close with the advent of gene cloning. This provided a way of analysing the structure of the genes in the genome, and thus identifying the control regions which are postulated to be adjacent to the genes and are presumed to associate with polymerases and controlling proteins. The cloning of the ovalbumin gene has been dominated by the work of two groups, those of O'Malley in Texas and Chambon in Strasbourg. The first step for both was to clone the structural gene obtained from mRNA. In O'Malley's laboratory, this led first to the elucidation of the sequence of the mRNA, in collaboration with George Brownlee at the MRC Laboratory of Molecular Biology, Cambridge, and was obtained just at the time that the Fothergills in Aberdeen were putting the finishing touches to the polypeptide sequence (McReynolds *et al. Nature* **273**, 723; 1978). Chambon's group concentrated its attention on the genomic structure, and they were amongst the first to observe the presence of non-translated intervening sequences (introns) in the genes coding for polypeptides in eukaryotes (Breathnach *et al. Nature* **270**, 314; 1977; Deol *et al. Nucl. Acids Res.* **4**, 3701; 1977). The precise details of these intron/exon arrangements then rapidly became clear from the work of both Chambon's and O'Malley's groups (see for example, Garapin *et al. Cell* **14**, 629; 1978; Dugaiczky *et al. Nature* **274**, 328; 1978; Gannon *et al. Nature* **278**, 428; 1979). The sequence which appears in the cytoplasm as messenger is interrupted in no less than seven places in the genome by DNA sequences varying from about 0.3 to 1.4 kilobase pairs. All but one of these

interruptions are found in the 5' half of the molecule which, because of the long 3' untranslated region of ovalbumin mRNA, puts them all in the coding region. The remaining intron is in the 5' untranslated region. A great deal of information has been obtained about features of the system which are shared with other genes, such as the presence of RNA precursors of messenger which are tailored to the final structure (Roop *et al. Cell* **15**, 671; 1978; Chambon *et al. Proc. 11th Miami Winter Symp.* in the press) and the nature of the sites in the RNA which are recognised by the processing enzyme (Catterall *et al. Nature* **275**, 510; 1978; Breathnach *et al. Proc. natn. Acad. Sci. U.S.A.* **75**, 4853; 1978). There are, however, other features which, while so far peculiar to the oviduct genes, must be taken into account when considering the question of eukaryotic genome organisation.

The function of introns in eukaryotic structural genes has been the subject of much speculation, and perhaps the most acceptable suggestion is that they flank regions of the gene coding for domains in the polypeptide to which portions of the total function of the protein can be ascribed. It is postulated that the genomic DNA regions coding for these domains have been brought together during evolution by a process involving the introns (Sakano *et al. Nature* **277**, 627; 1979; see *News and Views* **277**, 598; 1979). However, it is hard to see how this applies to ovalbumin. No specific functions have been ascribed to this protein. It may have important nutritional, hydrodynamic or other similar properties in relation to maintaining the developing embryo, but no function has been described or postulated which would require the cooperation of seven separate functional domains in the polypeptide. However, the function of the first intron of the ovalbumin gene must certainly be different since it lies in the 5' untranslated region of the mRNA and so has no relationship with any functional domains of the polypeptide. (Breathnach *et al. Proc. natn. Acad.*

Norman Carey is Director of Research, G. D. Searle & Co. Ltd, High Wycombe, Bucks.

*Sci. U.S.A.* **75**, 4853; 1978; Royal *et al.* this issue of *Nature*, page 125). Similarly, in the ovomucoid gene, a large number of exons has been found in the genomic DNA coding for a small protein which seems unlikely to have a complicated function requiring the assembly of a series of polypeptide domains (Catterall *et al.* *Nature* **278**, 323; 1979). Nevertheless, the polypeptide domain hypothesis remains an attractive one and it is possible that domain reassortment has occurred during the evolution of the oviduct proteins, but for reasons unrelated to the function of the polypeptide.

The latest piece of work in this fascinating series is published in this issue of *Nature* and is another tour de force from the powerful teams of Chambon and Kourilsky. Clearly, if there is any feature of the eukaryotic genome which resembles an operon in relation to hormonal induction, features in the DNA regions surrounding the ovalbumin gene would be expected to reveal it. Chambon and Kourilsky have therefore begun to 'walk along' the genome proceeding outwards from ovalbumin. To do so, they have used a new generation of recombinant DNA vectors called 'cosmids' which combine some properties of plasmids with the high efficiency of bacteriophage *in vitro* DNA packaging procedures, giving a very efficient selection of recombinants containing large sections of foreign DNA. Various partial digests of the chicken genome were cloned by Chambon and Kourilsky and were selected by hybridisation to a probe which covers the 5' region of the genomic ovalbumin gene, both introns and exons. Two clones are described in some detail. One, pAR1, starts within the third ovalbumin intron and extends for a total of 17 kb pairs in the 3' direction, about 12.5 kb pairs being outside the ovalbumin gene. The second, pAR2, is a 30 kb pair fragment which extends in a 5' direction from within the ovalbumin gene, and includes its first four exons. The two fragments thus cover a total of about 46 kb pairs, and overlap within the ovalbumin gene, which occupies about 7.7 kb pairs.

Certain peculiarities in the hybridisation data led the group to question whether the regions which they had cloned contained any other genes which are expressed in the oviduct. This was assessed by hybridising the total poly(A)-containing RNA from oviducts with the clones, and examining the hybrids in the electron microscope. No other genes were found on the 3' side of the ovalbumin gene; that is in the pAR1 clone, but two were found on the 5' side in pAR2. They are named X and Y, gene X being the most distal from ovalbumin, and its 5'

region seems not to be present in the clone but the RNA which hybridises to it is 2,400 nucleotides long. Gene Y RNA is about 2,000 nucleotides long, near to the size of ovalbumin mRNA, and the gene, like ovalbumin, has seven introns. The first intron of gene Y is close to the 5' end, in both X and Y all the introns are in the 5' half of the gene, and the exons of X, Y and ovalbumin are of similar size. This similarity of intron-exon pattern is not all. Parts of these genes cross hybridise with each other, and both with parts of the ovalbumin gene, which accounted for the hybridisation peculiarities which set the work on their trail in the first place. The conclusion is that there are sequence homologies in parts, but not all, of the expressed regions of all three genes.

There is also good evidence to show that the expression of all three genes is under hormonal control. The messengers are present in oviducts from birds treated with oestrogen but disappear when the hormone is withdrawn. The quantitation of this expression awaits further work, but the indications are that X and Y are only expressed to a small extent compared with ovalbumin. Although the data are not presented, the authors state that neither X nor Y codes for any of the other abundant oviduct proteins conalbumin, ovomucoid or lysozyme, but which proteins they do code for, and whether the messengers are in fact translated in the oviduct, remains unknown for the present. There is a great similarity between the organisation of the ovalbumin-related genes and that of the human  $\beta$  globin-related genes (see Little *et al.* *Nature* **278**, 227; 1979), where four genes (two  $\gamma$  genes,  $\delta$  and  $\beta$ ) of similar intron pattern are found close together on the genome. In the case of both gene sets, the 5' to 3' orientation of the genes is the same, and they are transcribed in the same direction. A further interesting feature is that the genes of each set are not expressed to the same extent under the same conditions, ovalbumin predominating over X and Y in the oestrogen-treated oviduct, and the  $\beta$  globin expression varying with the life cycle or disease state. We may now expect that information on the relatedness of the exons of the ovalbumin cluster will be useful in suggesting how these genes were assembled during evolution. The hybridisation data indicate that some exon regions of ovalbumin, X and Y, are closely related whereas others are more distantly related. The fine details of this relationship, perhaps including comparisons with other avian species, should indicate whether the genes have been assembled in parallel during evolution from a mixture of closely

related and unrelated regions, as the hybridisation data seem to suggest. In that case, the similarity in size of the exons may turn out to be coincidental. Alternatively, the cluster may have arisen by duplication of an ancestral gene, thus fixing the intron-exon pattern from the outset, but leaving the need to find an alternative explanation for the differing relatedness of the exons.

As for hormonal control, it has to be admitted that we are as yet no further ahead in our understanding. However, the close proximity to the genome of genes which are expressed to different extents under the influence of one hormone poses the question of whether transcription of the genes is initiated separately and with differing efficiency commensurate with the messenger abundance, or whether they are transcribed to the same extent by the same polymerase, operon fashion, with subsequent processing and stabilisation accounting for the differing levels in the cell. In other words the time may now be approaching when workers in the field can return to the study of the kinetics of the induction process with some real hope of testing the hypotheses. □

## Histocompatibility antigens and cytoskeletal elements

from Franklin H. Portugal

MAJOR histocompatibility antigens designated as H-2 in mice and HLA in man are cell-surface glycoproteins whose movement in the plasma membrane appears to be associated with the movement of intracellular cytoskeletal elements. These antigens are involved in such immune reactions as allograft rejection and recognition of viral and tumour antigens by syngeneic cytotoxic thymus-derived (T) lymphocytes. Initially, it was difficult to isolate even a few micrograms of pure HLA antigen from human splenic lymphocytes. Observations that the surface of cultured human lymphoblastoid cells contains a greatly enhanced antigen concentration simplified this problem and resulted in the isolation of milligram amounts of material. In 1975, Peterson *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **72**, 1612; 1975) proposed that the large chain for H-2 and HLA antigens, already known to carry the alloantigenic determinants, has both

Franklin H. Portugal is a science writer at present working on a history of the Carnegie Institution of Washington.

chemical and physicochemical properties similar to those of immunoglobulin. These antigens also contain a smaller chain which consists of  $\beta_2$ -microglobulin, is invariant, and shows homology to various IgG heavy and light chain homology regions. Because major histocompatibility antigens are found on the surface of virtually all normal, nucleated cells in man and mice, probably all mammalian cells have an immunoglobulin-like molecule on their surface. By solubilising H-2 antigen with either a proteolytic enzyme (papain) or detergent, Henning *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **73**, 118; 1976) showed that the amino-terminal end of the heavy chain extends away from the cell surface whereas the carboxyl-terminal end is associated with the cell membrane. Further characterisation indicated that H-2 antigen consists of a light-chain  $\beta_2$ -microglobulin (12,000 daltons) and a heavy polypeptide chain (46,000 daltons) that carries both distinctive antigenic determinants as well as a carbohydrate prosthetic group (Edelman *Science* **192**, 218; 1976). Similar studies with HLA-A antigen showed that it contained a light chain of  $\beta_2$ -microglobulin (12,000 daltons) and a heavy polypeptide chain (44,000 daltons) containing both antigenic specificity and carbohydrate (Springer & Strominger *Proc. natn. Acad. Sci. U.S.A.* **73**, 2481; 1976). Springer and Strominger proposed that a hydrophobic region of the heavy chain is inserted into the cell membrane so that the amino-terminal portion of the chain extends outside the cell and the carboxyl-terminal portion extends into the cell interior. By using the lactoperoxidase-catalysed iodination of the inner surface of lymphocyte plasma membrane, Walsh and Crumpton labelled HLA and showed therefore that this antigen is a transmembrane protein (*Nature* **269**, 307; 1977).

How the structure of these antigens and their insertion in the cell membrane may affect immune reactions can be studied with liposomes. Littman *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **76**, 902; 1979) have prepared unilamellar phosphatidylcholine liposomes containing H-2 antigen. In these liposomes, H-2 antigen was found to be integrally inserted in the membrane, oriented with the amino-terminal end of the chain facing away from the cell surface, and antigenically active. Such antigen-containing particles can also be used in assays with T lymphocytes.

Antigen movement over the cell surface is detectable by patching and capping phenomena. Bourguignon and Singer used a double fluorescence technique for staining both surface-bound H-2 antigen on mouse splenic T lymphocytes and for staining intracellular mechanochemical proteins such as actin or myosin (*Proc. natn. Acad. Sci.*

*U.S.A.* **74**, 5031; 1977). When the surface-bound receptors collected in patches in response to an external multivalent ligand, the membrane-associated actin or myosin within the cell also accumulated in patches directly under those of the receptor. This suggests that H-2 glycoprotein becomes linked to the intracellular contractile protein, possibly through an integral class of proteins that are located in the plasma membrane of eukaryotic cells. Koch and Smith confirmed that there is an association between H-2 antigen and actin (*Nature* **273**, 274; 1978), although the question of whether the association is a direct or indirect one could not be resolved.

Pober *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **75**, 6002; 1978) have recently indicated how such an association between the intracellular domain of a transmembranous protein and the cytoskeletal protein may be regulated. Incubation of either transformed lymphoblastoid cells or peripheral blood lymphocytes with  $^{32}\text{P}_i$  resulted in the phosphorylation of HLA-A and HLA-B antigens. The site of phosphorylation

is a serine residue(s) located in the hydrophilic, carboxyl-terminal region of the heavy chain. Incubation of isolated membranes from transformed lymphoblastoid cells with  $[\gamma^{32}\text{P}]\text{ATP}$  also produced phosphorylation of HLA antigens. Because interaction with actin is known to occur with many proteins that are phosphorylated, the phosphorylation of HLA antigens may be the basis for regulating association with cytoskeletal elements.

Many questions remain to be answered in future experiments. One concerns what factors regulate the phosphorylation of these membrane proteins. The question of which serine residue(s) of HLA-A and HLA-B antigens are phosphorylated and the number of phosphate groups incorporated into each heavy chain requires further resolution. Presumably, HLA antigen binds to actin as does H-2 antigen but this also remains to be demonstrated. It is still unclear whether microfilaments or microtubules or both are the cytoskeletal elements involved in the association with transmembranous proteins.  $\square$

## Laser spectroscopy pins down Rydberg constant

from John E. M. Goldsmith

The availability of tunable laser radiation and associated nonlinear spectroscopic methods has revolutionised many areas of spectroscopy (for a review, see *High-Resolution Laser Spectroscopy* Ed. Shimoda, Springer-Verlag, Berlin, 1976). One notable example is the elimination of Doppler broadening in the observation of the Balmer-alpha line ( $n=2 \rightarrow n=3$ ,  $\lambda=656 \text{ nm}$ ) of atomic hydrogen with the technique of saturated absorption spectroscopy (Hänsch, Shahin & Schawlow *Nature* **235**, 63; 1972). The Doppler effect causes atoms moving with different speeds to appear to have different resonance frequencies, just as the apparent pitch of a train whistle changes as the train moves past the observer. Since the atoms in a gas have a wide range of velocities, and all of the atoms are observed using classical (linear) spectroscopic techniques, the net effect of the Doppler shift is to cause a broadening of the spectral line. With saturated absorption spectroscopy, only atoms that are not moving (or at least have no component of velocity along the laser beams) are observed, thus eliminating Doppler broadening. The increase in resolution obtained in this

manner makes it possible to observe the individual fine structure components of the Balmer-alpha transition.

The ability to resolve this fine structure has great importance for measurements of the Rydberg constant. The Rydberg, which is defined as an explicit combination of other fundamental constants  $R = \mu_0^2 m_e e^4 c^3 / 8h^3$ , is a cornerstone in the evaluation of the fundamental physical constants. The physical meaning of the Rydberg is most clearly seen in the simple Bohr theory, in which the energy levels of the hydrogen atom are given by the expression  $E_n = -hcR/n^2$ ,  $n=1, 2, 3, \dots$ ; the principal quantum number  $n$  labels the energy levels of the atom. Thus the value of the Rydberg constant corresponds to the energy required to ionise the ground state hydrogen atom.

Until 1974, the Rydberg constant was determined by measuring the wavelength of emission lines from cooled hydrogen, deuterium, tritium, or ionised helium discharges (see *Series, Contemp. Phys.* **14**, 49; 1974, for a review of these measurements). The fine structure components of the lines were not resolved because of Doppler broadening, so it was necessary to calculate the spectral lineshape produced by the blend of components. This caused an uncertainty in pin-

John E. M. Goldsmith is in the Department of Physics, Stanford University.

pointing the 'centre' of the emission line, and thus an uncertainty in the value of the Rydberg constant.

Resolution of the fine structure of the Balmer-alpha line with Doppler-free laser spectroscopy has made possible nearly two orders of magnitude improvement in the precision of the Rydberg constant, making it one of the (if not the) most precisely measured of all fundamental physical constants. The first Doppler-free measurement used saturated absorption spectroscopy with a pulsed dye laser to observe the hydrogen and deuterium  $2P_{3/2}-3D_{5/2}$  transitions. A d.c. discharge tube similar to Wood's original design was used to dissociate the hydrogen molecules and excite some of them to the  $n=2$  level. The Rydberg constant was determined from a measurement of the wavelength of this transition, using an iodine stabilised helium-neon laser ( $\lambda=633$  nm) as a wavelength standard. The value so obtained,  $R=109737.3143(10)$   $\text{cm}^{-1}$  (Hänsch *et al.* *Phys. Rev. Lett.* **32**, 1336; 1974), was an order of magnitude more precise than previous Doppler-broadened measurements.

Further improvement in the Rydberg constant has been aided by the development of narrowband continuous wave (cw) dye lasers, and suitable dyes for cw operation at the Balmer-alpha wavelength. Using a variation of saturated absorption spectroscopy (known as polarisation spectroscopy) with a cw dye laser, and replacing the Wood's tube with a mild helium-hydrogen discharge, it became practical to study the hydrogen  $2S_{1/2}-3P_{1/2}$  transition, which is weaker than the  $2P_{3/2}-3D_{5/2}$  transition, but also more than three times narrower. The wavelength measurement of this transition was facilitated by first determining the wavelength of an iodine reference line which by good fortune has a wavelength almost identical to that of the  $2S_{1/2}-3P_{1/2}$  transition. A measurement of this small wavelength difference then yielded the value  $R=109737.31476(32)$   $\text{cm}^{-1}$  (Goldsmith, Weber & Hänsch *Phys. Rev. Lett.* **41**, 1525; 1978), with a precision three times higher than obtained previously. A more precise measurement of the wavelength of this iodine reference line could immediately yield at least another twofold improvement in the precision of the Rydberg constant.

Another recent Rydberg measurement returned to the use of saturated absorption spectroscopy in a Wood's discharge tube, but with a narrowband cw dye laser. The wavelength of three hydrogen Balmer-alpha fine structure components were measured ( $2P_{3/2}-3D_{5/2}$ ,  $2S_{1/2}-3P_{3/2}$  and  $2P_{1/2}-3D_{3/2}$ ), with the iodine-stabilised helium-neon laser again used as a wavelength

standard. The weighted mean of these values yielded the result  $R=109737.31513(85)$   $\text{cm}^{-1}$  (Petley and Morris, this issue of *Nature* page 141).

The values and precision of Rydberg measurements from the past 10 years are summarised in the figure. The Doppler-free measurements clearly are much more precise than the earlier Doppler broadened measurements. It is more significant, however, that these three independent measurements agree very well with each other, but are only marginally consistent with the earlier determinations. The possibility of such a systematic error indicates the need for independent measurements of values such as the Rydberg constant. The excellent agreement of the three Doppler free determinations, performed in two laboratories on several Balmer-alpha fine structure components using varied techniques, is a strong indication that such a systematic error has been avoided.

Measurement of the Rydberg constant at the current level of precision is already hindered by uncertainties inherent in the  $^{86}\text{Kr}$  primary wavelength standard, which limit its useful precision to a few parts in  $10^6$ . This is an artificial difficulty, however, and can be avoided by using lasers stabilised to molecular transitions, such as the iodine-stabilised helium-neon laser, as interim wavelength standards. Direct frequency measurements have recently been extended into the infrared region of the spectrum, and frequency measurements in the visible may not be too far off. For measurements with a precision greater than 1 part in  $10^6$  it will probably prove necessary to work with an atomic hydrogen beam, so small energy level shifts caused by conditions in the discharge can be eliminated. The ultimate Rydberg measurement could come from a frequency measurement of a narrowband cw ultraviolet laser source ( $\lambda=243$  nm,  $\nu=10^{15}$  Hz) used to excite the  $1S-2S$  transition in hydrogen using Doppler-free two-photon spectroscopy (Hänsch *et al.* *Phys. Rev. Lett.* **34**, 307; 1975). The natural linewidth of this transition is about 1 Hz, so one

can conceive of a measurement of its frequency with a precision better than 1 part in  $10^{15}$ . Using modern atomic theory, it is necessary to apply several small corrections to the hydrogen energy levels calculated with Bohr's theory. With such a frequency measurement, the precision of the Rydberg constant would only be limited by the precision with which these small corrections can be calculated. □

## Ionic landmarks along the mitogenic route

from K. S. Koch and H. L. Leffert

Two ionic fluxes, akin to those initiating and transducing nerve impulses, may be essential regulators of animal cell proliferation. This idea emerged at a recent conference\* where many findings pointed to increased  $\text{Na}^+$  influx being an early, perhaps the initial, mitogenic signal, and to subsequent  $\text{Ca}^{2+}$  ion movement coupled to cyclic AMP formation being necessary for DNA replication.

Experiments using amiloride (a specific  $\text{Na}^+$  influx inhibitor) and  $^{22}\text{Na}^+$  showed that 'burst-like' influxes are needed to initiate DNA synthesis in sea urchin eggs after fertilisation (D. Epel, Stanford University), in rat hepatocytes *in vitro* after exposure to peptide growth factors including EGF (S. Cohen's epidermal growth factor) (K. S. Koch & H. Leffert, The Salk Institute), and in cultured mouse 'fibroblasts' after exposure to serum factors including vasopressin (E. Rozengurt, Imperial Cancer Research Fund, London). Similar fluxes appeared operative during phytohaemagglutinin-induced human lymphopoiesis (G. Kaplan, University of Ottawa) and veratridine-stimulated mitogenesis of cultured chick central nervous system neurones (C. D. Cone, Hampton Virginia VA Hospital).

Possible mechanisms by which growth factors stimulate  $\text{Na}^+$  influx were considered. G. Eisenman (University of California, Los Angeles) discussed current views of cation-selective channel functioning based on gramicidin models and proposed that certain mitogens directly form the  $\text{Na}^+$  channel—an idea awaiting experimental test. Indirect mitogenic actions on channel 'gating' mechanisms result-

\*Growth Regulation by Ionic Fluxes' was held on 13-17 March 1979 at the Kroc Foundation, Santa Ynez, California, and the proceedings will be published as a number of the *Annals of the New York Academy of Sciences*.

ing from altered surface potentials (C. Bergman, University of Paris); upon lateral diffusion of membrane proteins resulting from altered membrane potentials (M. Edidin, Johns Hopkins University) measured with lipophilic cations like triphenylphosphonium<sup>+</sup> (R. Kaback, Hoffman-LaRoche); and on cell-cell interactions resulting from altered electrical coupling (W. Loewenstein, University of Miami) were also discussed.

How might increased Na<sup>+</sup> influx stimulate proliferation? One attractive mechanism, generally consistent with the experimental results described, may be activation by intracellular Na<sup>+</sup> of the membrane Na<sup>+</sup>/K<sup>+</sup> ATPase 'pump'. Such changes are expected to alter Na<sup>+</sup> gradients across the surface membrane. The coupling of solute transport to these gradients through a membrane 'carrier'—presumably to stimulate biosynthetic pathways—was reviewed in detail by R. Crane (Rutgers University). He showed evidence for amiloride-sensitive Na<sup>+</sup> gradient-dependent glucose uptake into rabbit intestinal vesicles as well as reconstitution of this system with a purified protein, obtained from brush-border membrane fractions, inserted into liposomes. The effects of growth factors in Crane's vesicle systems are unknown. Another possible consequence of increased Na<sup>+</sup> influx studied in fertilised eggs—a Na<sup>+</sup>/proton exchange elevating intracellular pH—generated a lively debate between its proponent (Epel) and its antagonist (L. F. Jaffe, Purdue University). Epel speculated that small pH changes cause widespread alterations involving critical enzyme cascades and macromolecular polymerisations. Jaffe then described egg experiments where injected buffers that blocked alkalisation failed to block growth. F. M. Harold (National Jewish Hospital, Denver) added that disruption of proton gradients with carbonylcyanide m-chlorophenylhydrazone in bacterial systems failed to impair growth seriously. But the issue was not resolved, and the role of Mitchell's proton gradients as regulators of animal cell proliferation remains to be explored. Further consequences of increased Na<sup>+</sup> influxes were suggested by J. Piatigorsky (National Institutes of Health) and G. Koch (University of Hamburg) whose results with ocular lens and viral protein regulatory systems, respectively, raised the possibility of Na<sup>+</sup> and K<sup>+</sup> selective translational and/or post-translational controls. These inquiries may soon yield definitive conclusions, especially

if a factor isolated by G. Koch, a dialysable methionine-containing translational inhibitor released from ribosomes by high Na<sup>+</sup>, is purified and if Piatigorsky's applications of recombinant DNA technology are successful.

A fourth likely consequence of increased Na<sup>+</sup> influx was elegantly demonstrated by Jaffe who showed by the use of aequorin, a Ca<sup>2+</sup>-sensitive photoluminescent protein, the flow of a Ca<sup>2+</sup> 'wave' across the cytoplasm of a fertilised Medaka egg. If this 'explosive' wave was blocked by intracellular injections of Ca<sup>2+</sup>-chelators, DNA synthesis did not begin. Jaffe theorised that Ca<sup>2+</sup> 'currents', detected extracellularly by a 'vibrating' probe developed earlier in his laboratory, cause self-electrophoresis of membrane proteins for which evidence was presented (K. Robinson, National Jewish Hospital). Whether such Ca<sup>2+</sup> currents flow across somatic cells stimulated to divide is not yet known. However, a clear late G<sub>i</sub>-requirement for surface Ca<sup>2+</sup> movement was demonstrated—for a broad spectrum of normal cells *in vivo* and *in vitro*—without which deoxyribonucleotide, and consequently DNA, synthesis cannot occur (A. Boynton, NRC, Ottawa). These events are mediated by cyclic AMP and it was postulated that cellular ribonucleotide reductase function requires a phosphoprotein regulator whose formation depends on cyclic AMP-activated protein kinase.

Properties of nervous system and limb regeneration were reviewed by R. Moore (University of California, San Diego) and by Jaffe, respectively. An attempt was made to consider these processes with regard to the ionic events described above. Two provocative links were provided, first from Jaffe's evidence that chronically applied cathodal Na<sup>+</sup> currents stimulate partial limb regeneration in frogs and second, from F. Westall's (The Salk Institute) observations that proteolysis converts myelin basic protein into a mitogenic peptide whose sequence (Thr-Pro-Pro-Ser-Gln-Gly-Lys) is contained within the brain fibroblast growth factor (FGF) isolated by D. Gospodarowicz (University of California, San Francisco). Such findings immediately provide one explanation for nerve requirements in limb regeneration. Moreover, although Gospodarowicz showed that myoblasts, chondrocytes and fibroblasts proliferate in response to FGF, he argued that blastemal cells, from which regenerated tissue arises, may be this mitogen's natural target. Thus, Jaffe's Na<sup>+</sup> 'currents' in regenerating stumps might actually be driven by FGF-like mitogens released from crushed myelinated nerves.

The existence of two regulatory ionic

'landmarks' has interesting implications for understanding growth regulation in general. In animal cell systems, it helps to explain how sets of growth factors may act synergistically for it predicts that certain substances activate Na<sup>+</sup> influx while others act predominantly upon Ca<sup>2+</sup>-cyclic AMP coupling. Reason to believe that two-signal models are correct was presented for hepatocytes (K. S. Koch & Leffert; Boynton) and has been reported elsewhere for BALB/c 3T3 cells (see for example Stiles *et al.* *Proc. natn. Acad. Sci. U.S.A.* **76**, 1279; 1979). Furthermore, interference with the Na<sup>+</sup> flux system perturbs transitions from resting to growing states differently from interference with the Ca<sup>2+</sup>-cyclic AMP couple. The former seems to determine both the lag-duration (or 'onset' time) and the total numbers of responding cells (K. S. Koch & Leffert; Rozengurt) whereas the latter mechanism seems to regulate the rate of entry into S-phase (Boynton). These findings must be considered by any theory of growth regulation; single-event models are insufficient to account for such observations. Lastly, it seems that control of both events is defective in tumour cells (Cone; Rozengurt; Boynton) but the real significance of these observations remains to be determined. □

## Studying surfaces

from M. A. Chesters

RECENT progress in understanding the interaction of molecules with solid surfaces was a major theme of the ECOS2 Conference at Cambridge\*. Although the subjects covered included adhesion, Auger microanalysis and the chemistry of polymer surfaces, about 70% of the papers were concerned with chemisorption on metal surfaces. D. Tabor (Cavendish, Cambridge) in his opening address traced the history of surface science and urged that increased attention be paid to fundamental studies of liquid/solid and solid/solid interfacial phenomena. As it was the conference provided an excellent review of progress in fundamental studies of chemisorption, surface elemental analysis and surface structural analysis.

A major motivation for studies of chemisorption is the need to understand heterogeneous catalysis on a molecular level and two approaches to the problem of linking research on idealised systems to the behaviour of

K. S. Koch and H. L. Leffert are in the Cell Biology Laboratory, The Salk Institute, San Diego, California.

\*The Second European Conference on Surface Science was held at the Cavendish Laboratory and Churchill College, Cambridge, England, on 26–29 March 1979.

real catalysts were described by G. A. Somorjai (University of California, Berkeley) and R. J. Madix (Stanford University). Somorjai has pioneered work on high index (stepped) metal single crystal surfaces in an attempt to identify the types of active site involved in various catalytic processes. He described experiments carried out in an ultra-high vacuum system combined with high pressure cell, enabling metal single crystal catalysts to be characterised by low energy electron diffraction and Auger spectroscopy before and after catalysing reactions at pressures up to 200 atmospheres. Apart from this direct approach, molecular beam studies of reactive scattering from stepped surfaces revealed the importance of step and kink surface sites in breaking carbon-hydrogen and carbon-carbon bonds. Madix argued that surface intermediates important in reactions catalysed at high pressure and high temperature, may be isolated in chemisorption studies at low pressure and low temperature. He described the use of thermal desorption spectroscopy coupled with photoelectron spectroscopy to identify a surface formate intermediate in the decomposition of formic acid on Ag(110) and a surface methoxy intermediate in the decomposition of methanol on Fe(100).

In the measurement of surface reaction kinetics, molecular beam scattering remains the major technique and was reviewed by G. Ertl (München University). G. W. Rubloff (IBM, New York) described a rather more direct approach to the study of rapid surface reactions in which surface concentrations were monitored by ultraviolet photoelectron spectroscopy (UPS). The advantage of such a technique is that surface reactions which do not involve desorption of gas may be studied. Both B. I. Lunqvist (Chalmers University of Technology, Sweden) and T. B. Grimley (University of Liverpool) outlined theoretical formalisms for describing the dynamics of the interaction of atoms and molecules with solid surfaces which should pave the way for the calculation of sticking coefficients and the construction of chemisorption potential energy curves. The increased experimental and theoretical interest in studying the kinetics of reactions on well defined surfaces was particularly apparent at the conference. At the same time, there was an encouraging, continued trend away from purely 'technique-oriented' discussions, although this cannot be completely avoided in an area where new techniques abound.

The formidable problem of the elucidation of the geometrical and electronic

structure of metal-adsorbate complexes was discussed largely in the context of photoelectron spectroscopy. G. J. La Peyre (Montana State University) illustrated how the operation of the symmetry selection rule in UPS is revealed in angular resolved experiments using polarised radiation (PARUPS), thus allowing the symmetry of the ionised states to be determined. In a discussion of the requirements of a full theoretical analysis of photoemission from adsorbates, J. B. Pendry (SRC Daresbury Laboratory) remarked that if the theoretical analysis were straightforward we would learn little from the experiment! P. H. Citrin (Bell Laboratories) later reviewed the SEXAFS experiment in which the fine structure above an X-ray absorption edge, which results from diffraction of the photoelectron, may be analysed on a straightforward kinematical basis to yield accurate data on the relative positions of atoms surrounding the photoelectron emitter. Surface Extended X-ray Absorption Fine Structure is detected through modulations in the Auger yield from the absorbing atom to achieve surface sensitivity, and Citrin illustrated the power of the technique by reporting results for iodine adsorbed on silver and copper single crystal surfaces. The chief disadvantage of SEXAFS is that a synchrotron radiation source is essential, so we shall be hearing much more of the technique as storage rings dedicated as photon sources become operational.

In the past few years there has been a resurgence of electron energy loss spectroscopy (EELS) as a means of studying vibrational modes of adsorbed species. This is in large measure attributable to H. Ibach (KFA, Jülich) and he gave an account of its application to the study of hydrocarbon adsorption on nickel surfaces. The technique involves the measurement of small energy losses (40–500 meV) of electrons impinging on a solid surface which arise through excitation of vibrational modes of the surface and of adsorbed molecules. The sensitivity is about two orders of magnitude higher than for reflection absorption infrared spectroscopy. Ibach was able to show some striking differences between the reactivity of a flat Ni(111) surface and a stepped Ni[5(111)×(1 $\bar{1}$ 0)] surface towards acetylene and cyclohexane. R. F. Willis (ESTEC, The Netherlands) has carried out a detailed investigation of the W(100)/hydrogen system in which he has pioneered the use of EELS in both specular scattering and diffuse scattering modes for which different selection rules apply. He described a detailed model for a reconstructed surface in which tungsten-hydrogen-tungsten bridges are tilted

out of the surface plane. The apex angle of the bridge and the tilt angle were determined from the frequencies and angular dependences of the three hydrogenic vibrational modes. Clearly EELS can supply some of the basic structural information on adsorbates which has proved so elusive and will be a vital complement to the other electron spectroscopic techniques in the future.

There is a continuing debate on the relevance of these idealised investigations to 'real' problems in surface science (see Tompkins, *Chemistry in Britain* **15**, 194; 1979). For myself the conference was preaching to the converted. I leave others to make their own judgement. □

## Birds as agricultural pests

from John Krebs

THE male bullfinch not only looks beautiful; it can be trained to whistle German folk tunes, and given the chance it will strip half the fruit buds off a pear tree in 90 minutes. It was this last attribute which brought the bullfinch to the attention of a recent meeting on birds as agricultural pests.\* J. M. Flegg (East Malling Research Station) reviewed the damage caused by bullfinches, redpolls and other birds to fruit crops, and pointed to some common sense factors influencing the level of destruction. Orchards planted next to natural woodland are more likely to suffer bullfinch damage as the woodland provides a good home base for the birds. Alder trees planted as windbreaks draw in redpolls to feed on the cones, and when the cone supply is exhausted the birds switch to devouring fruit buds; and the habit of removing all the herbaceous weeds from orchards may increase bullfinch damage, since the bullfinch prefers weed seeds and only switches to fruit buds when seeds are not available.

Farmers have tried to alter the food preferences of bird pests for hundreds of years. Although older methods such as rubbing garlic or pigs' dung on fruit trees are now outmoded, a modern equivalent is to try and condition birds to dislike crop foods by treating the crop with a chemical which makes the birds feel sick. This kind of aversive conditioning is well known to induce

\*The Symposium on 'Understanding Agricultural Bird Problems' was organised by the British Crop Protection Council and Agricultural Science Service at Royal Holloway College, 4–5 April 1979. The proceedings are to be published (by the British Crop Protection Council) as a book edited by E. N. Wright, I. Inglis & C. J. Feare.

M. A. Chesters is in the School of Chemical Sciences, University of East Anglia, Norwich.

'bait shyness' in rats and J. Rogers (US Fish and Wildlife Service) reported that it also works with birds. In laboratory trials, red-winged black-birds would avoid eating a foodstuff for more than 16 weeks after first encountering it mixed with the insecticide methiocarb, and this conditioned aversion was effective even when the only alternative food was highly unpalatable. Large scale field trials showed that methiocarb can reduce bird damage to vineyards by something like fivefold.

I. Inglis (Pest Infestation Control Laboratory, Worplesdon) described the efficacy of different kinds of visual scaring devices. The traditional scarecrow, and popular modern equivalents consisting of bright coloured miniature windmills are totally ineffective, and Inglis suggested that a knowledge of the behaviour of pest species is useful in designing more effective bird-scarers. For example, when a wood-pigeon is frightened and takes to the air, it reveals conspicuous white wing patches which might be seen by other pigeons as a danger signal. This led Inglis to try out the deterrent effect of pairs of pigeon wings lying on the ground, and in one study birds were largely deterred from landing in a clover field for up to 70 days by the sight of pigeon wings on the ground. Similarly, Brent geese were discouraged from landing in a field by putting out model geese in an 'alert anxiety' posture. One of the most effective deterrents of all is the sight of a man flapping his arms up and down like a giant eagle, and there is now available on the market a 7-foot high Incredible Hulk with mechanical flapping arms. All these scaring devices suffer from the problem of habituation: birds eventually learn to stop flying away from them unless occasionally reminded with a gun that there is a real danger. It may turn out in the end, as suggested in one of the discussions, that the best solution to bird scaring is the one recommended in 1668 by Gervais Markham in *Farewell to Husbandry*: "The only best and safest means to prevent this evil is to have' evensome young boys with bows and arrows to follow the seedman and harrows, making a great noise and shooting his arrows where he shall see these devourers aleight, not ceasing but chasing them from the land".

The meeting also touched on a more fundamental ecological issue raised by all techniques of scaring, deterring, or luring away bird pests: what happens to birds when they are frightened off a particular field? If they go next door, the problem is merely shifted on to someone else. One possibility, discussed by M. Owen (Wildfowl Trust, Slimbridge) is to provide refuges for birds,

## The leaning tower

from Ian Smalley

BECAUSE the Tower of Pisa was built very slowly, with many interruptions, it still stands; had it been completed during the 12th century it would probably have collapsed (Mitchell, Vivatrat & Lambe *J. Geotech. Eng. Div. Amer. Soc. Civ. Eng.* **103**, 227; 1977). Work on the foundations of the tower began in August, 1173 and the first story was completed in 1174. When the tower reached a height of three and a half storeys and a load of 9,840 metric tons in 1178 the work stopped. The work stoppage has been attributed to politics, to the heavy work load of the constructors, and to construction difficulties. Construction was not resumed until almost a century later and then the tower was completed up to the eight storey level, and to a total load of 13,728 t, during the period 1272-1278. Work then stopped again and did not resume until 1360 when the final storey was added and the whole tower completed in 1370. By the time of the final stage of construction the lean of the tower was significant and the centre line of the topmost part was changed on account of this.

Mitchell *et al.* concluded that the bearing capacity of the soils underlying the tower was never exceeded. The total settlement of the tower is due to the sum of four components: an immediate compression of the sands in a 7 m thick zone underlying the base of the tower, immediate compression of a 30 m thick clay layer underlying the sands, consolidation of the clay layer and secondary compression of the clay layer. They were unable to show, using their classical soil mechanics methods, why the tower actually leans although they suggested that this might be due to the higher compressibility of the foundation sand on the south side of the tower. Veder (*Bauingenieur* **50**, 204; 1975) had suggested earlier that the stone blocks used in the construction were stored on the south side of the tower causing an asymmetric loading.

Although the tower leans to the south now, it seems to have pointed

in various directions during its construction. From 1173 to 1178 two-thirds (in terms of weight) of the tower was constructed and it tilted towards the north-east. By the time construction resumed in 1272 this inclination had doubled. Inclination increased for a further 6 years at which time 86% of the final weight was in place. The tower then leant towards the north-west, and in 1370 when the tower was completed its inclination was towards the south, as it is today. The tilt was 1/31 in 1370 but today it is around 1/10 and, after a deceleration of movement for five and a half centuries, movements are today tending to accelerate. Much of the recent movement can be related to the removal of water from nearby wells and the lowering of the piezometric head in the deep sandy layer (Mascardi *J. Geotech. Eng. Div. Amer. Soc. Civ. Eng.* **104**, 299; 1978).

Cambefort (*J. Geotech. Eng. Div. Amer. Soc. Civ. Eng.* **104**, 156; 1978) has calculated that the tower will be stable until the year 2780, as long as the pumping from the deep aquifer does not increase beyond the 1966 rate. He has also proposed an ingenious lever mechanism to halt the tilt and fix the tower in its present position; a lever arm extending 12.3 m from the tower centre and a load of 600 t would apparently provide the necessary counterforce. Alternative solutions to the engineering problem are however still being sought; and there is still no consensus on what actually caused the tilt. Perhaps the most ingenious theory is still that advanced by Kerisel (*Geotechnique* **25**, 433; 1975) who invoked the Coriolis force due to the rotation of the Earth. Is it possible, wondered Kerisel, that a structure with a very low safety factor might be influenced by sustained small forces acting over several centuries?

Ian Smalley is with the Soil Engineering Section, DSIR Soil Bureau, Lower Hutt, New Zealand.

and an alternative is the one mentioned earlier in the context of bullfinches, to provide a different food supply. These courses of action may, however, exacerbate the problem. If a

John Krebs is a Lecturer in Zoology at the Edward Grey Institute of Field Ornithology University of Oxford.

pest species survives better as a result of the provision of refuges or alternative food supplies, it may return in great numbers in future years to attack agricultural crops. This kind of problem cannot be resolved without more knowledge of the factors determining survival and movements of bird pests. □

## One or more Eemian interglacials?

In a recent paper (*Nature* 277, 189; 1979) we described the Fjøsanger (interglacial) Stage in western Norway, and correlated it with deep sea oxygen isotope stage 5e and the Eemian of continental Europe. Bowen (*News & Views* 277, 171; 1979) accepted the former correlation but criticised the latter, because he agrees with Kukla's proposal (*Earth Sci. Rev.* 13, 307, 1977) that the Eemian represents three different interglacials.

The vegetational development in different interglacials may have been so similar that a separation on palynological evidence is impossible. However, this is not necessarily so, and the crucial point in the present discussion is whether other interglacials repeated the distinct pollen sequence so far being considered as the criterion for the Eemian.

We fully agree with Bowen's statement that the deep sea oxygen isotope stratigraphy proves that the classical subdivisions of the Quaternary of Europe are incomplete. That is our challenge! However, an incomplete continental stratigraphy does not imply that all previously defined units are ambiguous.

Bowen claimed that Weigank (*Geologie* 21, Beiheft 77, 1; 1972) has described two Eemian interglacials in superposition in northern Germany. On the contrary, however, he stated that these two interglacials can be identified on the basis of their pollen stratigraphy, the younger being the Eemian, and the older the Rügenian (=Kap Arkona in Frenzel's classification).

Most important Bowen stated that Kukla (*op. cit.*) has demonstrated that the classical Eemian sites in Europe were deposited during three different interglacials. No doubt, Kukla made an extremely interesting analysis of the Quaternary stratigraphy of Europe, but we cannot accept his evidence for more than one Eemian. Chiefly on the basis of geomorphological observations he postulated that the Saalian s.l. is composed of three distinct glacials, and he used Eemian sites for the presumptive interglacials so created. Most West German geologists (Düpphorn *et al.* *Eiszeitalter u. Gegenw.* 23/24, 222; 1973) reject the existence of an interglacial within the Saalian s.l., but

there are other more probable candidates (Rügen, Dömnitz/Wacken) to fill the milder intervals (see Weigank *op. cit.*; Erd *Palaeogeogr.*, -*clim.*, -*ecol.* 8, 129; 1970; Frenzel *Eiszeitalter alter u. Gegenw.* 23/24, 321; 1973; Menke & Behre *Eiszeitalter u. Gegenw.* 23/24, 251; 1973; Cepek *Ber. deutsch. Ges. geol. Wiss., A. Geol. Paläont.* 12, 375; 1967) than the Eemian, even if Kukla's interpretation is correct.

The main evidence in support of our thesis that the typical Eemian pollen sequence represents only one interglacial can be summarised as follows. Many known Eemian sites are located inside the Weichselian ice border; all of them are situated below till or disturbed by ice. More than 100 Eemian sites are known outside the Weichselian ice border, and, as far as we know, not a single sequence is reported to be below till, or below another interglacial. However, many 'not Eemian interglacials' are known below till outside the Weichselian ice border.

We conclude that our present knowledge strongly suggests that the Eemian pollen sequence of Europe represents only one interglacial, which is the Last Interglacial.

JAN MANGERUD

EVIND SØNSTEGAARD

HANS-PETTER SEJRUP

Department of Geology,  
Allégt. 41,  
5014 Bergen-Universitetet,  
Norway.

D. Q. BOWEN REPLIES: The points raised by Mangerud *et al.* are only valid in so far as the chronostratigraphy advocated by Kukla and others is incapable of direct validation at present. But the fact remains that the system they advocate and defend in the case of 'Eemian' is based on assemblage floras, a biofacies basis inherently unreliable as a result of its diachronous nature. Indeed by advocating that Woillard's (*Quaternary Res.* 9, 1; 1978) St Germain Interglacials, I and II, are time-equivalent to interstadials in the Netherlands and Denmark, also urged by Wijmstra (in *Climatic Change* (ed. Gribbin) Cambridge, 1978), they tacitly acknowledge the fragility of this bio-

facies approach.

Discrimination of specific interglacials on the basis of either being covered by till or not in relation to postulated glacial limits is no improvement on 'count from the top' methods criticised by Kukla. In this way the current conventional wisdom, or model chronostratigraphic schema, is maintained. Data are not only interpreted on such model terms but are frequently acquired and systematised according to its pigeon-holed ready-made classification—the 'reinforcement syndrome' of the late Norman Watkins (*Comments on Earth Sci. Geophys.* 2, 36; 1971). In the case of Weigank's work the significant point relates to his demonstration that the foraminiferal faunas of the Eemian and Rügenian Interglacials show only minor differences.

The fact is that, according to present interpretation (Shackleton & Opdyke *Quaternary Res.* 3, 39; 1973) and defining the base of the Middle Pleistocene at the Brunhes-Matuyama boundary (Butzer *Quaternary Res.* 4, 136; 1974), some eight interglacials occurred from that time to the present. It is pertinent to note that one of the UK working parties on International Geological Correlation Programme Project 24 is examining evidence to determine how many interglacials there have been since the Hoxnian. Conventionally there is only one—the Ipswichian (Eemian)! In the search for greater complexity in continental records it is inevitable that some degree of data manipulation will occur initially because many of the basic facts regarding Pleistocene geology are still inadequately known. For too long has it been assumed that the Pleistocene geology of most formerly glaciated areas is known—perhaps it is, at least according to the terms of existing models. But in terms of modern lithostratigraphic standards (Hedberg *Int. Stratigraphic Guide*, New York, 1976) this work, with some notable exceptions (Willman & Frye *Illinois Geol. Surv. Bull.* 94, 1970), has hardly commenced. In the meantime, other than by rare geochronometric dating, progress will inevitably include some manipulation born out of an expediency dealing with inadequate data.

## A hundred years ago

We need not insist on the extreme importance and interest of the exhibition which was opened last night at the Albert Hall, and for which extensive preparations have been making for

some time. The public mind both in this country and abroad has been recently much agitated on the question of electric lighting, and, as might be expected, people are much confused among the many systems which have been brought forward, and even those

who know something on the subject must find it difficult to make up their minds. Hence the importance of bringing together the various systems of electric lighting in such a way as to make comparison possible.

## Facts and hypotheses of molecular chemical tunnelling

Vitalii I. Goldanskii

Institute of Chemical Physics of the Academy of Sciences of the USSR, Vorobjevskoje Shausse, 2-b, Moscow, 117334, USSR

*The similarities and differences between electron-nuclear tunnelling (discovered in 1966) and molecular tunnelling (discovered in 1973) are described here in terms of radiationless electron transitions. Examples of the low-temperature limit on a chemical reaction rate, observed since 1973, include: growth of chains of polymerisation of formaldehyde, Fe-CO rebinding in haem-containing proteins, isomerisation of radical pairs, hydrobromination of ethene, and photoinduced conversion of rhodopsin into prelumirhodopsin. The general significance of molecular tunnelling for chemistry and related subjects is discussed. The possible manifestations of molecular tunnelling in the formation of complex molecules at the surfaces and in the bulk of 'dirty ice' mantles of dust grains in interstellar dense clouds are also considered.*

ONE of the most important consequences of the wave properties of matter is tunnelling—the ability of particles to penetrate the potential barriers whose heights exceed the particles' kinetic energy; the sub-barrier region is therefore classically forbidden for such particles.

Tunnelling starts to become important when the de Broglie wavelength of a particle becomes comparable to the barrier width in a way that the probability of tunnelling decreases with an increase of the width ( $d$ ), the height ( $E$ ) of the potential barrier, and the mass ( $m$ ) of the tunnelling particle.

The tunnelling concept had its first successful application in nuclear phenomena such as  $\alpha$ -decay<sup>1,2</sup>, spontaneous fission, and thermonuclear reactions and later greatly contributed to solid state physics, electronics<sup>3-5</sup> and more recently to cosmology<sup>6</sup>.

### Chemical conversions

Such concepts in chemistry were initially concerned with the delocalisation of particles between two identical potential wells<sup>7</sup>, and led to analysing theoretically the tunnelling contribution to chemical reaction rates<sup>8-11</sup>. Such contributions should be particularly significant at low temperatures because—in accordance with Arrhenius' law—the rate of classical transitions over the barrier decreases exponentially with decreasing temperature while the probability of simple sub-barrier tunnelling should level off as  $T \rightarrow 0$ , rather than drop towards zero.

The quite general criterion of a 'tunnelling temperature'<sup>21</sup> is given by  $T_t = (\hbar/k_B \pi 2^{1/2} d)(E/m)^{1/2}$  where  $k_B$  is the Boltzmann constant. For  $T < T_t$  tunnelling starts to dominate exponentially the Arrhenius-type transitions and the rate of exothermic reactions in many common problems gradually reaches its low-temperature plateau.

Generally an exothermic transition  $i \rightarrow f$  requires the mixing of an initial level  $U_i^0$  with final levels  $U_f^n$  and the dissipation of the transition energy  $\Delta U_{if}$  provided by the fast electronic-vibrational relaxation of the final state (with the rate of such dissipation being larger than the rate of transition itself).

Different theoretical treatments lead either to the limit of the statistically averaged rate of such transitions or to their complete disappearance at low temperatures. Hence tunnelling does not necessarily produce the low-temperature plateau of chemical conversion rates, however, its occurrence is a very strong argument in favour of the quantum tunnelling mechanism of these conversions.

For several decades the search for chemical tunnelling was restricted to the region of comparatively large temperatures ( $T > T_t$ ), and conclusions about its existence were based on minor (up to tens of per cent) isotope effects in the rate of conversion of hydrogen-containing and deuterated compounds<sup>13</sup>.

However, even stronger kinetic isotopic effects in such conversions (up to factors of  $\exp(500/T)$ ) still do not confirm tunnelling because they can be caused simply by differences in zero-vibrational energies of Z—H and Z—D bonds.

Experimental observations of chemical tunnelling began in 1966 when Chance *et al.*<sup>14,15</sup> discovered the low-temperature (120–4 K) plateau (at  $W \sim 300 \text{ s}^{-1}$ ) of the reaction rate of the laser-flash initiated oxidation of cytochrome *c* by chlorophyll. Using the simplest model of tunnelling as being a penetration of a plane wave through the one-dimensional barrier and taking the pre-exponential factor as  $\omega_e \sim 4 \times 10^{15} \text{ s}^{-1}$  (Gamov factor  $G_t = (W/\omega_e) \sim 10^{-13}$ ) and the activation energy  $E \approx 0.14 \text{ eV}$  (as obtained from experiments up to 300 K) Chance *et al.*<sup>14,15</sup> estimated the tunnelling length of an electron as  $l \approx 30 \text{ \AA}$ . A similar value could be obtained by comparing the position of the low-temperature plateau with the tunnelling temperature  $T_t$  defined above.

Calculated tunnelling lengths of such an order of magnitude are also typical of many other examples of low-temperature transfer of electrons—in biopolymers and in irradiated frozen glasslike solutions—if they are treated simply using Gamov factors and assuming that the barrier height equals the activation energy in a high-temperature region.

However, such tunnelling resembles an electron current

Fig. 1 Scheme of electron-nuclear tunnelling for electron transfer from the donor (D) to the acceptor (A). a, The tunnelling of electron over the distance  $l$  (levels in D and A do not usually coincide). b, The displacement of nuclei over the distance  $d$  for the transition of the electron  $e(D) \rightarrow e(A)$  indicated by vertical arrow.

through the thin dielectric layer which breaks the electron circuit rather than the transfer of reactants in the chemical reaction.

The general situation is much more complex because chemical tunnelling of electrons is related to the displacement of nuclei and we need to consider possible violations of the Franck-Condon principle. This was noted for the first time by Libby<sup>16</sup>, and was later analysed in several studies<sup>17-20</sup> of the tunnelling of electrons in oxidation-reduction interactions of ions in solutions and in electrode reactions.

After Chance's discovery<sup>14,15</sup>, when it seemed necessary to consider the electronic-vibrational interactions (vibrational coupling), the Franck-Condon factors in the tunnelling-type oxidation-reduction transformation of complex bimolecules were based on ideas of radiationless electron transitions (see refs 21-25). Different descriptions of electron tunnelling in biopolymers as generalised electron-nuclear tunnelling are described in refs 26-30.

In 1973 the discovery of a low-temperature limit of the rate of complex chemical reactions was first reported<sup>31,32</sup> using the example of the growth of polymerisation chains of formaldehyde, FA (see also refs 33-35).

We shall emphasise here that the words 'chemical reactions' describe transformations which include the reconstruction of molecules, the spatial rearrangement of atoms, changes in all main characteristics of valence bonds, their multiplicities and nature ( $\sigma$  or  $\pi$ -bonds) as well as lengths and angles.

The theoretical treatment of this phenomenon<sup>31,32</sup> as a new kind of molecular chemical tunnelling used the Siebrand's theory<sup>36</sup> of radiationless relaxation of electronically-excited molecular states. Later this theory was also extended to the case of molecular tunnelling, the so-called tunnel-polaron non-Arrhenius chemical reaction kinetics<sup>37</sup>.

Numerous surveys have been devoted to tunnelling of electrons in chemistry and biology (see refs 38-40) and we touch here only briefly the theory of such tunnelling to emphasise both the similarities and the differences of electron-nuclear and molecular tunnelling.

The probability of a radiationless electron transition  $W_{if}$  is determined by the product of the matrix element of the electron

transition  $L_e^2 = |\langle \psi_{ei} | \hat{L} | \psi_{ef} \rangle|^2$  and of the Franck-Condon factor  $F_v = |\langle \psi_{vi} | \psi_{vf} \rangle|^2$ :

$$W_{if} = (2\pi/\hbar) L_e^2 F_v \rho_f = \omega_{eff} F_v$$

where  $\psi_e$  and  $\psi_v$  are the electron and vibrational wave functions respectively,  $L$  is a transition operator such as the non-adiabaticity operator and  $\rho_f = (\hbar\omega_f)^{-1}$  is the density of vibrational levels in the final state.

The wave functions  $\psi_e(x)$  are proportional to  $\exp(-x/\alpha)$  for  $x > \alpha$ , where  $\alpha \sim \hbar/(2mE)^{1/2}$  is the damping parameter, that is the size of the region of localisation of electron density, which is close to the length of chemical valence bond  $a$  (at  $E \sim 1$  eV).

The wave functions  $\psi_v(x)$  are proportional to  $\exp[-(x/\Delta)^2]$  for  $x > \Delta$ , where  $\Delta = (\hbar/M\omega)^{1/2}$  is the amplitude of nuclear vibrations;  $\omega$  is the frequency of these vibrations;  $M$  the mass of the nuclei.

Among the most important parameters of electron and molecular tunnelling are the lengths of tunnelling (generally configurational displacement) given below as  $l$  for electrons and as  $d$  for heavy particles.

In most cases of electron-nuclear tunnelling in oxidation-reduction processes<sup>26-30</sup>:  $l \gg \alpha \approx a \gg d \approx \Delta$ .

The long-range transfer of electrons from the donor to the acceptor is not accompanied by chemical reaction. Displacements of donor and acceptor nuclei proceed in a similar way to ordinary intramolecular radiationless transitions up to distances of the order of  $\Delta \sim 0.1$  Å (see Fig. 1).

In the case of molecular tunnelling in chemical reactions we have  $d \approx l \approx a \gg \Delta$ .

For sufficiently large electron ( $l \gg \alpha$ ) and nuclear ( $d \gg \Delta$ ) displacements, when the matrix elements of the transition probability are determined by the asymptotics of wave functions, the matrix element of the electron transition transforms into the ordinary Gamov-type tunnelling factor, that is  $L_e^2 \propto \exp[-\psi l(mE)^{1/2}/\hbar]$  ( $m$  is the electron mass,  $\psi \sim 1$  depends on the shape of the barrier), while the vibrational (nuclear) Franck-Condon factor depends exponentially on the square of the nuclear displacement:  $F_v \propto \exp[-(d(M\hbar\omega)^{1/2}/\hbar)^2]$  (here  $\omega = \omega_i \ll \omega_f$ )<sup>35</sup>.

Parameters of various processes interpreted in terms of radiationless electron transitions are summarised in Table 1.

Just as Chance's discovery<sup>14,15</sup> is generally regarded as a first experimental proof of the existence of chemical electronic tunnelling, various examples of a low-temperature plateau of the rate of chemical reactions can be considered as experimental confirmation of the existence of molecular chemical tunnelling.

The first such example as mentioned above was the discovery of a limit (below  $\sim 12$  K) of the rate of growth of chains in

Table 1 General characteristics of processes interpreted in terms of radiationless electron transitions

	$l$	$\omega_{eff}/\omega_0^*$	$d$	$F_v$	$W_{exp}(s^{-1})$
1. Electron-vibrational relaxation	$\sim \alpha$	$> 10^{-3}$	$\sim \Delta$	$> 10^{-3}$	$10^{14}-10^8$
2. Tunnelling of electrons in oxidation-reduction conversions:					
(i) not taking into account the nuclear displacement;	$(10-30)\alpha$	$< 10^{-8}$	0	1	$10^6-10^{-2}$
(ii) taking into account the electronic-vibrational coupling	$< 10\alpha$	$< 10^{-5}$	$\sim \Delta$	$> 10^{-3}$	
3. Molecular tunnelling in chemical reactions:					
(i) 'pure' molecular tunnelling;	$\sim \alpha$	$> 10^{-3}$	$\sim a$	$< 10^{-4}$	$10^{10}-10^{-4}$
(ii) tunnel-polaron transitions	$\sim \alpha$	$> 10^{-3}$	$d_i \sim \Delta$ $\sum d_i \sim a$	$> 10^{-3}$	

\*  $\omega_0^* = 10^{14} s^{-1}$  is a typical value of pre-exponential factor in chemical reactions.

**Fig. 2** The upper simplified scheme shows positions and displacements of molecules of solid formaldehyde and the polymer chain. The lower scheme illustrates the tunnel transitions of  $\text{CH}_2\text{O}$  groups during polymerisation ( $b_1 \rightarrow a$ ) and during filling up of 'vacancies' formed near the end groups of polymer chain during polymerisation ( $b_2 \rightarrow b_1$ ). The curve  $a$  is the adiabatic curve for a formaldehyde molecule added to a growing polymer chain;  $b_1$  is a similar curve for the initial monomer molecule, and  $b_2$  represents a similar curve for the next monomer molecule (the zero on the  $x$ -axis for this curve has been shifted by a distance  $\Delta d$ ). The energy of dissociation of the C-O bond is  $D \approx 4$  eV, energy of the sublimation of crystalline FA is  $\Delta H_s \approx 0.3\text{--}0.4$  eV, polymerisation heat  $Q \approx 0.37$  eV, activation energy  $E = 0.1$  eV. Note that the product  $\Delta d(M_{\text{CH}_2\text{O}}E)^{1/2}$  is close to the corresponding value for spontaneous fission of atomic nuclei, where  $\Delta d \approx 10^{-12}$  cm and  $E \sim 1$  MeV.

radiation-induced polymerisation of solid formaldehyde<sup>31-35</sup> studied by calorimetric method between 140 and 4 K.

Stacks of planar triangles of monomer  $\text{CH}_2\text{O}$  molecules with double  $\text{C}=\text{O}$  bonds transform in this reaction into long chains of single tetrahedral

bonds, and the substitution of van der Waals radii of C and O (typical for monomers) by much shorter valence  $-\text{C}-\text{O}$  bonds in polymers leads to a considerable ( $\sim 40\%$ ) increase in density. The scheme used for the calculation of the tunnelling rate in formaldehyde polymerisation is illustrated by Fig. 2.

In such an analysis the rate of growth of the polymer chain depends exponentially on the square of the molecular tunnelling distance  $(\Delta d)^2$  of the monomer group. Besides the addition of new links to the growing chain, the polymerisation includes in this calculation the subsequent stage of delocalisation of the cavity formed at the border between the end link of the polymer chain and the neighbouring monomer molecule—provided, for example by quantum diffusion<sup>41-43</sup>.

Another variant shown in Fig. 3 is the replacement of a well-defined cavity between the polymer and monomer by an extended distorted region of variable density (such as the stretched end of a polymer chain or the 'swollen' monomer that fills the cavity) which plays to some extent the part of polaron-deformed region of the crystal and is transferred (following the transfer of 'driving' particle such as an electron) with the end of the growing chain, corresponding to the above mentioned tunnel-polaron variant of non-Arrhenius kinetics<sup>37</sup> listed—among the other mechanisms—in Table 1.

Adopting a complex (generally, multidimensional) picture of potential surfaces means we can consider the possibility of conversions through low barriers: in other words, the possibility of eliminating various restrictions on the tunnelling rate which

are in ordinary molecular tunnelling due to large masses or large displacements of reacting species.

The temperature dependence of the rate constant on the growth of polymerisation chains of formaldehyde is shown in Fig. 4.

The average time of adding one new link to the growing polymer is  $\tau_0 = k^{-1} = \tau/G$  (where  $\tau$  is the time taken for the growth of the whole chain and  $G$  the radiation-chemical yield of polymerisation) which is  $\tau_0 \approx 10^{-2}$  s at the plateau.

Frauenfelder *et al.*<sup>44-45</sup> confirmed the existence of molecular tunnelling in a study of low-temperature Fe-CO reconstitution in a haem-containing protein and protohaem. Fe-CO bonds were broken by lasers flashes and the kinetics of their reconstitution was spectrophotometrically followed over very wide intervals of time ( $10^{-6}$ – $10^3$  s) and temperatures (2–340 K).

Besides finding a low-temperature plateau below  $\sim 10$  K (see Fig. 4) these observations demonstrated the complex, polychromatic character of these kinetics, that is the existence of broad spectra of activation energies and barrier widths rather than single values of these parameters.

The polychromatic kinetics described in refs 48–49 and later combined with the tunnelling concepts<sup>50,51</sup> is typical for systems with many different reactant states represented, for example, by different conformers of proteins or by traps of different depths in irradiated molecular solids.

Frauenfelder *et al.*<sup>44-47</sup> successfully used polychromatic kinetics to solve the complex picture of several potential barriers hindering Fe-CO reconstitution and to correlate these barriers with the structures of protohaem, myoglobin and haemoglobin.

The low-temperature rate limit of the processes studied by Frauenfelder *et al.* was also demonstrated by Mössbauer absorption spectroscopy<sup>52,53</sup>.

Meanwhile using Mössbauer emission spectroscopy (in particular, on combining it with the technique of delayed  $\gamma\gamma$ -coincidences) allowed electron-nuclear tunnelling to be observed which caused the change of state of metallic ions in iron-cyanide<sup>54</sup> and cobalt-phenantrolyne<sup>55</sup> complexes.

A Japanese research group<sup>56</sup> has recently extended the earlier ESR observations<sup>57</sup> of conversions of radicals in  $\gamma$ -irradiated dimethylglyoxime at 77–220 K to lower temperatures (4–77 K) and succeeded in finding the low-temperature plateau of the rate of the comparatively slow process of isomerisation of radical pairs (see Fig. 4) which is characterised at higher temperatures

**Fig. 3** The adiabatic potential curves for the normal ( $a$ ) and 'stretched' ( $b$ ) groups of polymer chains and  $\text{CH}_2\text{O}$  molecules in the crystal of a monomer. In the case of a well-defined hole the curves  $a$  and  $b$  represent two neighbouring states separated by a potential barrier (shown in the figure) which prevents elementary chain growth. In the case of a 'stretched' polymer chain there are two possible intermediate states:  $(ab)_1$  and  $(ab)_2$  between  $a$  and  $b$ . Any barriers are absent in transitions of the type  $b \rightarrow (ab)_2 \rightarrow (ab)_1 \rightarrow a$ .

by an activation energy  $E \approx 0.65$  eV. Having studied the kinetics of hydrobromination for an equimolar ethene-HBr mixture between 90 and 30 K, our group observed long ( $\nu \sim 200$ ) chains of this reaction even<sup>34,58</sup> at 30 K. Subsequent calorimetric investigations of stationary and non-stationary kinetics of chain hydrobromination in the conditions of predominantly quadratic or linear rupture of chains led<sup>90</sup> to the numerical determination of the rate constant of propagation of chains ( $k_p = \tau_0^{-1} = G/\tau$ ) and to finding another example of the limit of the rate of elementary chain reactions at low temperatures (see Fig. 4).

Application of picosecond laser spectroscopy to the studies of photo-initiated rhodopsin-prelumirhodopsin conversion<sup>59</sup> has demonstrated once more a low-temperature reaction rate plateau.

However, there is no agreement about the mechanism of this process: there exist two main approaches, namely the tunnelling of one or two hydrogen atoms to the nitrogen or Schiff base (across a distance of 0.5–0.9 Å)<sup>59</sup> or the low-temperature *cis-trans* isomerisation of the chromophore group (retinal) bound to the protein (opsin)<sup>60–62</sup>.

The large reaction rate at the plateau ( $K_H \approx 2.8 \times 10^{10} \text{ s}^{-1}$ ) and a quite weak kinetic isotopic effect ( $K_H/K_D \approx 7$ )—see Fig. 4—remind us of the possibility of a tunnel-polaron mechanism<sup>37</sup> of low-temperature isomerisation—via several states represented by intermediate potential curves in Fig. 3. Confirmation of this idea would be highly significant to the problems of low-temperature quantum chemistry, therefore, it is very important to make a definite choice between the transfer of hydrogen atoms in rhodopsin and the isomerisation of retinal.

The tunnelling of atoms and molecules with a rearrangement of chemical bonds should not be treated as exclusive to low-temperature chemistry. Such tunnelling can also be observed as sub-barrier predissociation of molecules by very precise laser tuning of their excitation energy below the Landau-Zener gap (this possibility was mentioned in ref. 38) or by electron

beams<sup>63</sup>. Isotopic differences in the probabilities of such tunnelling may be useful for isotope enrichment.

One of the new topics of macroscopic chemical kinetics which could result from tunnelling is the cold initiation of thermal explosions by high pressures which enhance the tunnelling as well as the possibility of oscillations between subcritical and overcritical states of the system compared with the conditions of thermal explosion.

It is also possible that in some cases the usual transition from the diffusion to the kinetic region with decreasing temperature will be supplemented by a return to the diffusion region below the tunnelling temperature—because of the gradual disappearance of temperature dependence on the rate of the kinetic stage of conversion.

The high selectivity of low-temperature tunnelling reactions caused by the interplay of the three main parameters— $d$ ,  $M$  and  $E$  may be advantageous for applied cryochemistry and cryobiology.

The persistence of chemical reactivity even near absolute zero makes it doubtful whether a complex organism could be brought back to life after being subjected to prolonged freezing in conditions when chemical chain reactions might be initiated by external agents like radiation.

Of special interest is the possibility of chemical and prebiotic evolution at very low temperatures when exothermic reactions (including the formation of highly complex products) are thermodynamically favoured (because all entropy restrictions are eliminated as  $T \rightarrow 0$ ) and at the same time—in spite of the Arrhenius law—quantum effects permit measurable, finite rates of chemical conversions.

The problem of cold tunnelling evolution from the 'storage of negative entropy' up to prebiotic levels has been discussed previously<sup>30–34,64–66</sup>. The possibility of tunnel-polaron-type<sup>37</sup> low-temperature exothermic reactions of various kinds (such as polymerisation and polycondensation) could be particularly significant.

## Interstellar chemistry

In view of all these circumstances we now consider the role of low-temperature quantum effects of chemical kinetics in the formation of complex products of interstellar chemistry. However, we should emphasise that—in contrast with the experimental facts and theoretical considerations described above—the following comments are purely hypothetical and they are intended to stimulate discussions and new experiments. The problems of interstellar chemistry have been treated in many recent surveys (see refs 67–77, 91), and we will consider them only to the extent needed for discussing the possibilities of molecular tunnelling in interstellar chemical reactions.

The most abundant element in the Universe is hydrogen. The cosmic abundance of helium (relative to hydrogen) is 0.09, followed by oxygen ( $7 \times 10^{-4}$ ), carbon ( $3 \times 10^{-4}$ ), nitrogen ( $9 \times 10^{-5}$ ), then magnesium, silicon and iron ( $\sim 10^{-4}$  altogether). Amongst almost 50 interstellar molecules detected by radio and optical spectroscopy the most widespread apart from  $\text{H}_2$  are: CO ( $\sim 10^{-4}$ ),  $\text{NH}_3$ , HCN and HNC ( $\sim 10^{-6}$ ). There is no doubt that water and methane are also well represented in interstellar space, and we should also mention formaldehyde ( $\sim 10^{-8}$ ) whose low-temperature polymerisation was directly observed in the laboratory.

The main stage of interstellar chemistry is the multitude of so-called interstellar clouds—giant ( $10^{17}$ – $5 \times 10^{19}$  cm) suspensions of dust grains in a gas medium. The total dust amounts to only about 1% of the gaseous mass; dust grains are generally assumed to consist of central 'cores' ( $r \geq 10^{-6}$  cm) of silicates or graphite surrounded by mantles of 'dirty ice' ( $r \sim 10^{-5}$  cm) formed by a mixture of frozen substances. The average number of hydrogen atoms per dust grain in the cloud is  $10^{12}$ .

One of the main differences between diffuse ( $n_{\text{H}} \sim 10$ – $10^3 \text{ cm}^{-3}$ ) and dense or dark ( $n_{\text{H,H}_2} \sim 10^3$ – $10^7 \text{ cm}^{-3}$ ) clouds is the following: diffuse clouds are transparent to UV radiation which causes ionisation of atoms and dissociation of molecules, while

**Fig. 4** Summary of data on the low-temperature limits of rate constants ( $\text{K s}^{-1}$ ) of chemical reactions ( $\log K$ – $\log T$  coordinates). Curve 1 ( $\Delta$ ), growth of chains of polymerisation of formaldehyde. Curve 2 ( $\circ$ ), reconstitution of Fe–CO bonds in  $\beta$ -haemoglobin. Curve 3 ( $\square$ ), isomerisation of radical pairs in  $\gamma$ -irradiated dimethylglyoxime. Curve 4 ( $\circ$ ), propagation of chains in the hydrobromination of ethene. Curve 5 ( $\times$ ), photoinduced conversion of rhodopsin into prelumirhodopsin. Curve 6 ( $\times$ ), photoinduced conversion of deuterated rhodopsin into prelumirhodopsin.

dense clouds are opaque to UV radiation. Therefore photodissociation does not proceed in the depths of dark clouds and a much wider variety of complex,  $m$ -atomic molecules (up to  $m = 11$ , cyanotetra-acetylene  $\text{HC}_9\text{N}$ ) are present here. This is why dark clouds are also referred to as molecular clouds. The temperature of dust grains in these clouds is  $T = 10\text{--}20\text{ K}$ .

The outer regions of dark clouds are transparent to UV radiation (its flux  $\mathcal{F}_{\text{UV}} \sim 3 \times 10^8 \text{ cm}^{-2} \text{ s}^{-1}$  and its cross-section for interaction with molecules is  $\sigma_{\text{UV}} \sim 10^{-18} \text{ cm}^2$ ), and each molecule absorbs a UV quantum within  $\tau_{\text{UV}} \sim 100 \text{ yr}$ .

The only external agents which can ionise or excite molecules inside the clouds are energetic cosmic protons. They interact with each interstellar molecule within  $\tau_p \sim 3 \times 10^9 \text{ yr}$ . This value strongly exceeds not only  $\tau_{\text{UV}}$ , but also the lifetime of the clouds themselves which has been determined by their collisions and by gravitational collapse to be  $\tau_{\text{cl}} \sim 10^5\text{--}10^7 \text{ yr}$ .

In discussing interstellar chemistry we need to consider three types of chemical reactions—in the gas phase, at the surfaces of dust grains, and in the bulk of dirty ice. Tunnelling plays no part in gas phase reactions and they will not be considered here.

As far as reactions at the surfaces of dust grains are concerned, most attention has been paid to the activationless recombination of free atoms and radicals<sup>69,70,75</sup>. According to existing estimates<sup>70</sup> tunnelling can play an important and even decisive part in lateral diffusion processes which precede such recombination for physically and chemically adsorbed hydrogen atoms and for heavier atoms and radicals in the case of their physical adsorption.

What this means to molecular tunnelling (or tunnel-polaron transitions) as a possible mechanism of chemical reactions at the surface and in the bulk of dust grains, has been discussed recently<sup>64,65</sup>. An analysis of the possible role of tunnelling in such conversions should take into account the competition between the chemical reactions of complex molecules (components of dirty ice), their ejection from surfaces into the gas and their destruction by interstellar radiation which can not only decompose more complex molecules into simpler species but also initiate exothermic chain reactions of molecular combination for example, polymerisation. The destruction effects of radiation seem to restrict the formation of complex,  $m$ -atomic molecules in gas-phase reactions and in the recombination of radicals at grain surfaces to  $m \sim 10\text{--}12$ . Therefore such reactions cannot account for the formation of more complex interstellar molecules—up to polymer size.

Meanwhile astrophysicists such as Sagan<sup>73,76</sup>, Greenberg<sup>72,77,78</sup>, Wickramasinghe<sup>79,80</sup> and Hoyle<sup>81–83</sup>, although differing in their conjectures and conclusions about the nature of very complex interstellar molecules and their origins, nonetheless agree that such molecules do exist in the interstellar dust. These conclusions are based both on laboratory analyses of products of low temperature UV illumination of solid mixtures resembling the dirty ice<sup>73,77,78</sup> (however, these analyses were performed after defrosting such mixtures, and therefore indicated the products of not only the 'cold' reactions but also of their after effects) and on the comparison of galactic absorption and emission IR spectra with the laboratory spectra of trial compounds<sup>79–83,76</sup>.

Sagan considers the tar-like macromolecular compounds of irregular composition and structure formed in his laboratory model experiments as likely interstellar compounds and called<sup>76</sup> them tholins.

After comparing various terrestrial and interstellar IR spectra Hoyle and Wickramasinghe arrived at some interesting although controversial conclusions about the formation of interstellar polymers of formaldehyde, of polyoxymethylene<sup>79,80</sup> and even of polysaccharides<sup>81–83</sup>.

All these authors agree that the formation of any polymer requires the growth of macromolecules in a chain reaction, but they differ in the astrophysical conditions deemed necessary for such chain reactions.

According to Sagan<sup>73,76</sup>, polymers and other sufficiently thermostable complex organic substances were transported into

the interstellar gas as components of grains ejected from solar nebulae by radiation pressure and stellar winds at the early stages of stellar evolution. Furthermore, tens of identified interstellar  $m$ -atomic molecules ( $m = 2\text{--}11$ ) were formed not in the usual processes of integration in the gas phase and at the surface of grains but as degradation products of more complex interstellar dust compounds. Although we shall not discuss this point of view here, it should be noted that polymers above a certain temperature  $T_d$  are quite often not truly stable but only metastable, when stabilised by endcapping groups (see ref. 84). Being formed below  $T_d$  such polymers remain stable even above  $T_d$ , but polymer chains will not grow at  $T > T_d$ .

Another idea is that the polymerisation (as well as the formation of complex molecules by recombination of radicals<sup>69,70,72,75,77,78</sup>) proceeds directly in the interstellar dust grains at  $T = 10\text{--}20\text{ K}$ , in the bulk of the ice mantles or at their surfaces. Even in the depths of dense clouds polymerisation chains can be triggered by long-range cosmic protons ( $E_p \geq 100 \text{ MeV}$ ). However, before the discovery of the low-temperature limit of the chemical reaction rate speculations about the hypothetical formation of polymers within dense clouds lacked kinetic grounds.

At present we can attempt quite a detailed analysis of such possibilities for at least one example, the polymerisation of formaldehyde.

## Interstellar polymerisation

Let us start with the abundance of formaldehyde in dirty ice. The saturated gas phase concentration of CO in equilibrium with solid carbon monoxide at 20 K is  $\sim 10^5 \text{ cm}^{-3}$ , and for methane  $\sim 1 \text{ cm}^{-3}$ . These values are larger or fairly close to the real concentrations of CO and  $\text{CH}_4$  in the interstellar gas which, in such circumstances, can be undersaturated. Therefore the freezing-out of  $\text{CH}_4$  (and especially of CO) seems to have much less significance on the formation of dirty ice than the solidification of ammonia, HCN, HNC, water and ethane.

Characterising the volatility by the temperature which corresponds to an equilibrium gas concentration of  $1 \text{ cm}^{-3}$ , then we have in order of decreasing volatility: ethane ( $\sim 35 \text{ K}$ ), ammonia and formaldehyde ( $\sim 60 \text{ K}$ ), HCN and HNC, then water ( $\sim 90 \text{ K}$ ) and, finally, a polymer of formaldehyde–polyoxymethylene ( $\sim 100 \text{ K}$ ). The rate of condensation does not depend on volatility while the rate of sublimation (both spontaneous and radiation-induced) decreases rapidly with diminishing volatility. Therefore these consequences accord with the steady-state enrichment of dirty ice by various components in comparison with gas. While the relative abundance of formaldehyde in the gas phase is no larger than several tenths of a per cent of all the other listed compounds, its abundance in the solid phase, in its polymer form, could be much higher. Moreover, we should consider that the above listed cosmic abundances of various elements provide only for water and formaldehyde the possibility to form the whole mass of dust grains (0.01 of hydrogen mass) while the maximum total mass of interstellar ethane is half of that, of HCN and of HNC a quarter of that, and of ammonia a sixth of that.

The attainment of steady-state conditions requires perceptible gas-solid transitions in both directions, that is a combination of condensation and sublimation. The condensation rate is high enough: the number of molecules of a certain kind condensed at each grain during the cloud life-time  $\tau_{\text{cl}}$  (years) is  $100 \kappa n \tau_{\text{cl}} (T/M)^{1/2}$ , where  $M$  is their molecular mass (in daltons);  $\kappa n \text{ (cm}^{-3}\text{)}$  their gas phase concentration ( $n = n_{\text{H}, \text{H}_2}$ ,  $\kappa \leq 10^{-6}$ );  $\epsilon \leq 1$  their sticking probability. For the most dense and long-lived clouds ( $n \tau_{\text{cl}} \geq 10^{12}$ ) the condensation can even lead to a several-fold increase of the masses of grains during the time that the cloud exists.

Estimates of the sublimation rate contain more uncertainties. The rate constant of spontaneous (thermal) evaporation of molecules bound to the surface with a binding energy  $D$  equals  $K_{\text{se}} \sim 10^{12} \exp(-D/k_B T)$ , and the time of such an evaporation of the surface monolayer would exceed the clouds

lifetime if  $(D/k_B) \geq 60 T$ .

Detailed estimates of the rate of induced evaporation caused by the transient heating of the entire grain by low-energy cosmic rays and, to a lesser extent, by the spot heating of the same origin are given in ref. 70.

According to these estimates the lifetime of clouds ensures numerous repetitions of evaporation of molecules physically adsorbed at the strange lining (at  $D \approx 0.05\text{--}0.1$  eV). However, the evaporation of mantle would be strongly hindered by its conversion to a crystal with greater binding energy. There will be no evaporation at all of molecules incorporated into the polymer chain. Therefore one can expect formaldehyde to be more abundant in the surface layers of interstellar grains because of its polymerisation.

The radiation-chemical yield of solid-state polymerisation of crystalline formaldehyde at 20 K is  $G \sim 10^4$  molecules per 100 eV of radiation energy<sup>31-35</sup>. Thus the energy delivered by cosmic protons to a grain during  $\sim 3 \times 10^5$  yr is already sufficient to cause its complete polymerisation if it were to consist exclusively of formaldehyde: mixed composition of dirty ice certainly hinders polymerisation. Nevertheless, although the active end group is surrounded from all sides but one by admixtures it will 'automatically' select the only possible direction to add the neighbouring monomer molecule. The formation of a new link of the growing chain at the surface can be preceded by several futile encounters of the end group with other molecules hitting the surface from gas phase or diffusing along the surface. It would be interesting for interstellar chemistry to compare the  $G$  values for low-temperature polymerisation initiated by electrons and  $\gamma$  rays (when the local heating along the tracks is insignificant), by protons, and by heavy ions (when the heating along the tracks is particularly strong<sup>85</sup>). It would also be desirable to determine directly the radiation yield of the evaporation of various molecules from different surfaces.

The rate of lateral diffusion of physically adsorbed molecules at low temperatures is determined by tunnelling and an estimate<sup>70</sup> of the time of a quantum jump of a molecule with  $M = 30$  gives  $t_{tr} \sim 0.1\text{--}1$  s. For the diffusion in the 'strange matrix' when the encounter of reactants requires  $N$  jumps, the reaction rate would be determined either by diffusion (at  $\tau_0 < t_{tr}$ ), or by kinetic factors (at  $\tau_0 > t_{tr}$ ), and the time of reaction would correspondingly be the time of  $N$  or of  $(N\tau_0/t_{tr})$  jumps. If the end group of a growing chain is surrounded only by its own monomer, the diffusion factors cease to play any part, and the possibility or impossibility of effective polymer accumulation in the interstellar dust grains is determined by the interplay of four characteristic times— $\tau_0$ ,  $\tau_{uv}$  (for diffuse clouds and outer layers of dense clouds), and  $\tau_{cl}$  (deep in dense clouds), as  $\tau_{cl} < \tau_p$ .

Consideration of these criteria leads to the following inequalities required for the realisation of chain reactions with chain length  $\nu$ , in dense clouds:

$$\tau_0 \ll (10^{-3}\text{--}10^{-2})\tau_{uv}/\nu \quad \text{or} \quad \tau_0 \ll \tau_{cl}/\nu$$

Taking the value of the pre-exponential factor  $\omega_0 \approx 10^{14} \text{ s}^{-1}$  one gets the following condition for the classical (Arrhenius-type) interstellar chain reaction to proceed:  $E < T(5.6 \times 10^{-3} - 2 \times 10^{-4} \log \nu)$  eV.

In the case of polymerisation of formaldehyde ( $\nu \geq 10^3$ ,  $E_{exp} \approx 0.1$  eV, refs 31-35) the inequality  $\tau_0 \ll 10^2\text{--}10^4$  yr would be fulfilled for Arrhenius kinetics only at  $T > 20$  K, while the experimental value is  $\tau_0 \approx 10^{-2}$  s, at  $T = 4\text{--}12$  K.

An approximate representation of the rate of tunnelling is obtained by using Gamov factors (see refs 37, 66):  $G_t = \exp(-\beta d(mE)^{1/2}/\hbar)$ . This yields the following condition for quantum (tunnelling) chain polymerisation of formaldehyde in dense clouds:

$$\beta d(mE)^{1/2}/\hbar < 4 - 0.15 \log \nu$$

where  $\beta = 2\sqrt{2}$  for a rectangular barrier,  $\beta = \pi\sqrt{2}/2$  for a parabolic barrier, and  $\beta = 4\sqrt{2}/3$  for a triangular barrier,  $d$  is in angstroms, and  $E$  in electron volts. This inequality corresponds to:  $d(E)^{1/2} \leq 60\text{--}90$  for the tunnelling of electrons,  $d(E)^{1/2} \leq 1.4\text{--}2$  for H atoms,  $d(E)^{1/2} \leq 0.35\text{--}0.5$  for formaldehyde mole-

cules in a monomer matrix.

In this way tunnelling could significantly increase the number of possible low-temperature reactions in dense clouds. One case would be, for example, the possibility of tunnelling polymerisation at the surface of dust grains with the formation of a very thin (several molecular layers) polymer film around the inner region of dirty ice. Such a film could protect the surface of this inner region from both condensation and sublimation.

For chemical and prebiotic evolution the reactions of polycondensation in dirty ice mantles with the participation of  $\text{CH}_2\text{O}$ , HCN, HNC,  $\text{NH}_3$  and  $\text{H}_2\text{O}$  are of interest. Such reactions lead to the formation of amino acids, polypeptides, sugars and nucleotide bases (purines and pyrimidines), they are exothermic, but not chain-type.

There are no reasons why there could be a 'pure' molecular tunnelling mechanism of such reactions—the rate of tunnelling falls steeply to a vanishingly small limit with increasing barrier widths and masses. However, each single step of a chemical conversion which represents an elementary gas phase process (such as the reaction  $\text{H}_2\text{C}=\text{O} + \text{NH}_3 \rightarrow \text{H}_2\text{C}=\text{NH} + \text{H}_2\text{O}$ ), proceeds in the solid as a sequence of many individual or collective conformational rearrangements of molecules, complexes or indeed whole regions of molecular crystals. The collision of a dust grain with a cosmic proton or UV quantum, or the release of recombination energy at the grain surface can induce the transfer of the 'driving' particle, such as the electron, which determines the number of conformational rearrangements. In this way the tunnel-polaron mechanism<sup>37</sup> becomes involved: the single long-range transfer of a molecule ( $d \approx a$ ) is replaced by several short-range displacements ( $d_i \approx \Delta$ ,  $\sum d_i \approx a$ ) which can lead to the lowering or even to the disappearance of the activation barrier (see Fig. 3), and to a reasonably high and temperature-independent rate of chemical conversions of cold systems such as of isomerisation. This mechanism could be important also for chemical and prebiotic evolution.

One should, however, bear in mind that if a certain product is formed as a final step in a non-chain sequence of  $\eta$  chemical conversions, and each of these conversions needs an external stimulus, then the yield of such product would be  $\eta\nu$  times smaller than the number of molecules entering the chain of length  $\nu$ . Therefore the yield of multistep polycondensation reactions accumulated during the life-time of dense clouds would not exceed 0.01% of the mass of the grains.

The formation of even the most complex biopolymers in interstellar dust grains does not guarantee their conservation during the later formation of new stars and planetary systems, when the dense clouds collapse. One can not exclude, for example, the strong heating at the surfaces of planets at certain stages in their evolution. Nevertheless, one should also keep in mind the variety of possible chemical reactants and reactions in 'warm' systems depending on their history. For example, polymers created and stabilised by endcapping at low temperatures could survive the consequent warming, but they cannot be formed directly at higher temperatures. Meanwhile the existence of such polymers opens additional possibilities of chemical conversions not only in cold, but also in warm systems, such as the integration of molecules in shock-wave induced solid-phase reactions<sup>86,87</sup> and in the vicinity of phase transitions, which proceed during the alternate heating and cooling of reactants<sup>88,89</sup>. Favourable conditions for the latter type would be provided, for example, by multiple transportation of stable organic compounds between circumstellar disks and interstellar clouds<sup>76</sup> and in comets with extended orbits which alternately suffer short heating when approaching the Sun, and prolonged deep cooling, away from the Sun.

The hypothesis of a cold 'entropyless' exothermic formation of complex molecules permitted only by quantum chemical reactivity is not an alternative, but an additional idea on the mechanisms of chemical and prebiotic evolution in terrestrial and extraterrestrial conditions.

I thank Professor V. A. Benderskii for stimulating discussions.

# New large-scale magnetic features of the Milky Way

M. Simard-Normandin & P. P. Kronberg

University of Toronto, Scarborough College and David Dunlap Observatory

*A large body of newly determined rotation measures (RM) for extragalactic radio sources gives a new, much clearer picture of the magnetic structure of our Galaxy. The RM sky is dominated by a very strong zone which extends to large (down to  $b \approx -40^\circ$ ) negative galactic latitudes. Both the strength and extent of this feature are greater than appreciated from earlier data. It coincides in angular position with loop II of the non-thermal radio background radiation of the Galaxy. This, and two other strong RM features suggest that our Galaxy has very large-scale magnetic field zones, probably between the spiral arms, and that the prevailing sense of the field is opposite in the interarm regions on each side of the Sagittarius arm.*

WE report the discovery of some new large-scale features of the galactic magnetic field which have been obtained from a programme to determine accurate rotation measures (RM) of a large sample of extragalactic sources.

Previous analyses of Faraday rotation<sup>1-7</sup> have shown that a systematic modulation of the RMs occurs with galactic coordinates ( $l, b$ ) and that RMs are systematically larger at low galactic latitudes. They also indicate a prevailing sense of RM consistent with a local magnetic field directed towards  $l \approx 90^\circ$  (refs 2, 4, 6, 7), a trend which also agrees with that deduced from the RMs of pulsars<sup>8</sup>.

Our new polarisation data have greatly improved the number and quality of RM determinations for extragalactic radio sources, and currently give 528 RMs. This is nearly a factor of 2 more than the number of previously published RMs of equivalent reliability. The increased density of sources on the

galactic ( $l, b$ ) sky provides us with the clearest picture yet obtained of the large-scale galactic contribution to the RMs.

### A large, high-latitude anomaly in the RM sky

Figure 1 shows the distribution in galactic coordinates of rotation measures of 476 extragalactic sources. This sample has been purged of 52 sources whose RMs, although accurately determined, are likely to be 'contaminated' by Faraday rotation in the sources themselves, rather than in the interstellar medium. We have established that sources with high depolarisation rates (that is, low  $\lambda_{1/2}$  values; see ref. 9) have systematically higher RMs. We have therefore removed sources with low  $\lambda_{1/2}$  ( $< 10$  cm), as this is an independent source parameter unlikely to be related to the effects of our Galaxy.

The most prominent feature in the RM sky is a large zone of negative RMs from  $b = +10^\circ$  to  $-40^\circ$  at  $45^\circ \leq l \leq 160^\circ$ . We shall denote this as region A. Although previous RM data showed the region centred near  $l \sim 90^\circ$  to have predominantly negative RMs, the large angular scale and strength of this region are revealed for the first time by our new data. Figure 1 shows that surprisingly large RMs, up to  $200 \text{ rad m}^{-2}$ , occur at negative latitudes as far as  $-30^\circ$  near  $l \sim 90^\circ$ . This contrasts with most other galactic regions, in which the RMs are small at  $|b| \geq 12^\circ$ .

### Other new zones of high RM off the galactic plane

To display the large-scale RM features better, we have calculated the average RM of neighbouring sources within a  $10^\circ$  radius of each source. Sources with RMs greater than  $1.3\sigma$  from the mean are omitted from the averaging calculation. Figure 2 shows the average RM centred on each source. Inspection of Fig. 2 reveals that there are two other zones of systematically large RM above  $|b| = 5^\circ$ ; one (region B), centred near  $l = 255^\circ$ , extends to negative latitudes  $b \sim -20^\circ$ , and has large positive RMs of up to  $300 \text{ rad m}^{-2}$ . A third high-RM zone (region C) at positive latitudes is centred at  $l \sim 40^\circ$ ,  $b \sim +5^\circ$ .

We note that in the south galactic hemisphere the prevailing RM sense as previously noted by Gardner, Morris and

Whiteoak<sup>2</sup>, and Vallée and P.P.K.<sup>5</sup>, is negative in  $0^\circ \leq l \leq 180^\circ$  and positive at  $180^\circ \leq l \leq 360^\circ$ . This trend continues from the galactic plane as far as the south galactic pole, and is reinforced by the present, larger RM sample. The overall trend of RMs in the northern galactic hemisphere (NGH) is less straightforward. At latitudes about  $+20^\circ$  the prevailing RM sense is positive for  $0^\circ \leq l \leq 90^\circ$  (which we denote as the first quadrant), and the sign alternates in successive quadrants in the NGH. One explanation of this pattern, which was also recognised by Gardner *et al.*<sup>2</sup> and Vallée and P.P.K.<sup>5</sup>, is that loop I (the North Galactic Spur, see ref. 10) seems to cause a perturbation of the local magnetic field on a large angular scale in the first and fourth quadrants ( $0^\circ \rightarrow 90^\circ$ , and  $270^\circ \rightarrow 360^\circ$ ) in the NGH. The outer two quadrants reflect the trend of RM present at southern latitudes.

### Rotation measures and the galactic loops

The perturbation of the RMs in the first and fourth quadrants and  $b > +20^\circ$  is consistent with a large magnetic loop associated with loop I which is the largest 'off-plane' feature of the galactic continuum radiation<sup>11</sup>. We can now establish the magnitude of this perturbation as  $\approx 30 \text{ rad m}^{-2}$ . This is much weaker than features A, B and C mentioned above. Feature C, being close to the plane, is probably not associated with loop I.

Loop III (ref. 12) in the northern hemisphere has no corresponding large-scale RM feature greater than  $\sim 20 \text{ rad m}^{-2}$  (Figs 1, 2). The fact that loops I and III do not appear as strong features in the RM sky is consistent with other evidence that they are local features.

Loop II (ref. 12), on the other hand, seems to encircle RM feature A. Whether or not this is merely coincidence is not clear, but we also note that region A coincides with a mild enhancement of the galactic continuum radiation. If loop II is similar in nature to loops I and III and if it is also associated with feature A, the very large RMs in A require it to be too large to be local. A mean RM at  $l = 90^\circ$ ,  $b = -25^\circ$  of  $-150 \text{ rad m}^{-2}$  implies, for  $\langle n_e \rangle = 0.03 \text{ cm}^{-3}$  and an aligned magnetic field of  $3 \times 10^{-6} \text{ G}$ , a scale length of 2 kpc. We conclude that if loop II is a local feature associated with loop III (which is directly on the opposite side of the galactic plane), then it cannot be associated with RM feature A. We consider that loop II is unlikely to be a local feature in view of its close angular coincidence with feature A.

Fig. 1 RMs of 476 extragalactic radio sources displayed on an equal area projection. Features A, B and C (see text) are labelled.

**Fig. 2** Mean RMs in circles of  $10^\circ$  radius centred on each source, which emphasise the large-scale variations better than Fig. 1. The RM scale is the same as that of Fig. 1. The positions of the radio continuum loops I, II and III are outlined. Note that some small-scale features which are real are smoothed out, and the precise location of boundaries where the RM changes sign are slightly masked. These are best located in Fig. 1.

The large scale of feature *A* (implied by its large RM) requires that it have a large magnetic energy,  $\gg 10^{52}$  erg. On this consideration alone, RM feature *A* is too energetic to be associated with a supernova remnant. On energetic grounds it could be associated with either galactic rotation or large-scale streaming of the infalling high-velocity HI clouds, of which there are several in the same direction<sup>13,14</sup>. It is possible that feature *A* is associated with local streaming effects which are related to the magellanic stream, because the end of the magellanic stream lies in the approximate direction of feature *A*. More data are required, however, to establish any connection with the magellanic stream.

### The structure of magnetic field

The large rotation measures observed near the galactic plane around  $l \approx 255^\circ$  (feature *B*) and  $l \approx 90^\circ$  are consistent with a longitudinal magnetic field directed towards  $l \approx 90^\circ$ . In the direction opposite to galactic rotation the large RM zone is centred near  $255^\circ$  rather than  $270^\circ$  which suggests that the Perseus arm may be opening up in this direction. The RMs and dispersion measures (DM) of pulsars in this direction indicate a mean magnetic field of less than  $3 \mu\text{G}$  ( $90^\circ$  and  $270^\circ$  south of the galactic plane). From this we conclude that the extent of the aligned field in both these areas (*A* and *B*) is greater than  $\sim 4$  kpc. *A* and *B* must therefore be large-scale features of the Galaxy. Feature *C* at  $l \approx 45^\circ$  can be interpreted as another major longitudinal component located approximately between the Sagittarius and the Norma-Scutum arms where (as the magnitude of the RM suggests) the prevailing field is directed along our line of sight for several kiloparsecs.

The very abrupt reversal of RM near the plane at  $l \approx 60^\circ$  is consistent with a model containing two prevailing field zones pointing in opposite directions along the spiral interarms. This is best shown in Fig. 3, in which we superimpose the model of the spiral structure of the Galaxy by Georgelin<sup>15</sup>.

The fields do not seem to be co-planar. They also extend to quite large angular distances from the mean galactic plane. An interesting question at this stage is whether a counterpart to, say, region *C* can be seen on the  $l < 360^\circ$  side of the Galaxy—in the southern hemisphere. Unfortunately, we have not made

measurements from the southern hemisphere, and have calculated RMs only from polarisation measurements in the literature for this region. It is now clearly of interest to obtain more data at  $|b| < 30^\circ$  in the range  $360^\circ \geq l \geq 260^\circ$ . This would verify if large-scale magnetic field components can be seen associated with arm or interarm regions on the southern side of the Milky Way.

**Fig. 3** A sketch of the regions containing an aligned component of magnetic field, indicating their approximate scale and direction. This is shown superimposed on the distribution of bright HII regions in the Galaxy by Georgelin<sup>15</sup>. Note that the heavy dotted and dashed lines do not necessarily represent the local prevailing magnetic field direction, but rather the zones in which the line-of-sight integral of RM is large and has the same sense.

RM of pulsars in the direction  $l = 60^\circ$  near the plane indicate a more turbulent field exhibiting several reversals along the line of sight. Interarm magnetic fields, on the other hand, tend to be more homogeneous, as suggested by the fact that there are virtually no small rotation measures in features *A* and *B*.

## Conclusion

We conclude that galactic loops I and III cause at most weak perturbations in the RM sky. Loop II may or may not be a local loop like loops I and III, depending on whether or not it is

associated with RM feature *A*. The latter must be at least 2 kpc and possibly as large as 6 kpc in length.

Weak fields ( $< 3 \mu\text{G}$ ) seem to occupy the interarm regions and maintain the same prevailing sense for distances of several kiloparsecs. A reversal of the prevailing field direction occurs near  $l = 60^\circ$ . The field direction seems to change abruptly as our line of sight crosses the Sagittarius arm. A more detailed and quantitative analysis of the galactic RM and magnetic structure will be published separately.

We acknowledge financial support from the NRC of Canada in the form of a grant (P.P.K.) and a scholarship (M.S.-N.). We also thank Stuart Button for assistance with the data processing.

*Major, minor and trace element analyses of glass from pumice and tuffs from the Koobi Fora and Shungura Formations show that the Chari, Karari and Tuff L are correlative; that the KBS Tuff and Tuff H2 are correlative; and that an unnamed tuff in the Koobi Fora Formation is correlative with Tuff H4 of the Shungura Formation.*

TWO important early Pleistocene hominid-bearing formations, the Koobi Fora Formation and the Shungura Formation, are found in the Lake Turkana Basin in northern Kenya and in southern Ethiopia, respectively (Fig. 1). These formations have yielded several hundred hominid specimens<sup>1,2</sup> and several thousand artefacts<sup>3,4</sup>. Despite almost 10 years of work in the region, there are no firm stratigraphic correlations between the two areas. Lack of exposure in the intervening area precludes correlations based solely on field studies.

Rhyolite tuffs, mostly reworked, occur in both regions and have served as marker beds for mapping, and have been useful for K–Ar dating. Over 100 tuffs occur in the Shungura Formation, and 12 of these are extensive enough to subdivide that formation into 12 members. The thick stratigraphic section, good exposure and small lateral facies variations have resulted in a well-established sequence<sup>5,6</sup>. The Koobi Fora Formation was deposited near the basin margin by different, smaller river systems that drained the Suregei Cuesta and the Chew Bahir

(Lake Stephanie) region<sup>7</sup>. Mapping of the Koobi Fora Formation has been hampered by poor exposure and rapid lateral facies changes. Independent dating and palaeontological studies in the two regions led to faunal correlations that, if acceptable, are very disconcerting<sup>8,9</sup>. If the chronologies of both formations were correct<sup>5,10</sup>, faunas of similar evolutionary stage are separated by 0.5–1 Myr. Subsequent dating of pumice from the KBS Tuff (1.8 Myr)<sup>11</sup> in the Koobi Fora Formation did not substantiate the original date of 2.6 Myr<sup>10,12</sup>. This discrepancy has led to additional studies<sup>13,14</sup> which disagree with the younger date.

Volcanic ash is an excellent correlative tool in Quaternary studies. Mineral suites, refractive indices of minerals and glass, and the chemical composition of glass have all been successfully used to correlate air-fall tuffs<sup>15,16</sup>. Reworked ash deposits, however, have additional complications. Erosion of pre-existing ash deposits and addition of pumice and glass from these deposits, abrasion of distinctive glass mantles on primary minerals and dilution of primary minerals by detrital minerals render several techniques useless. Primary minerals in Koobi Fora Formation tuffs are sometimes unrecognisable because of abrasion; electron microprobe studies of individual shards show that some tuffs are made up of several populations of shards with differing chemical compositions<sup>17</sup>. Because differing proportions of these populations would make trace element analyses of bulk glass samples of dubious value, the present study concentrated on characterising pumice fragments from tuffs because electron microprobe studies showed that the glass in a single pumice is homogeneous.

\* Present address: Environmental Sciences Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37830.

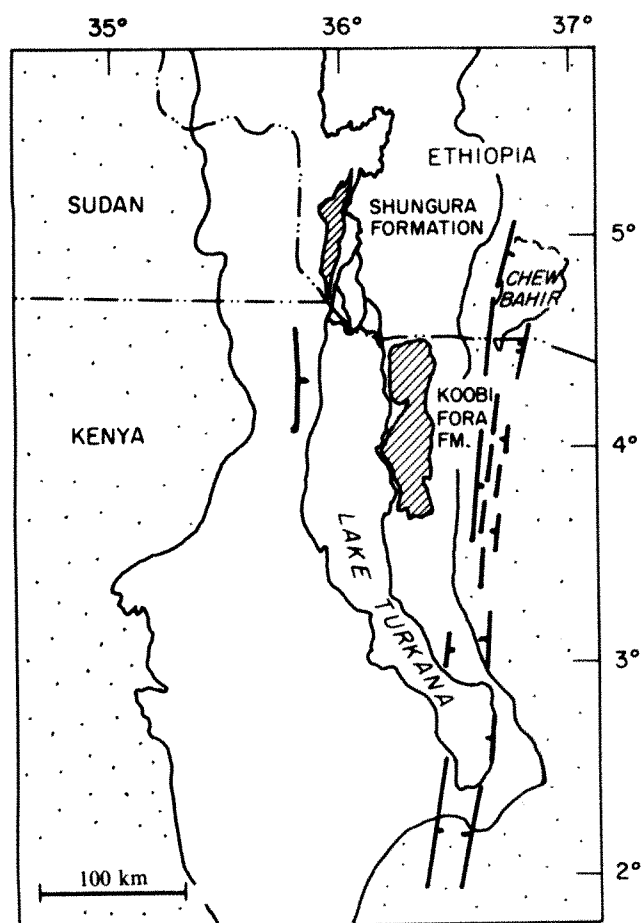

Fig. 1 Map of Koobi Fora and Shungura Formations.

## Procedure

Tuff and pumice samples were collected during several field seasons (1972–77). Pure glass separates from individual pumice were obtained by gentle crushing and sieving, treatments with HCl and HF in an ultrasonic bath to remove adhering clay and silt particles, and repeated magnetic separations. Heavy liquids were used only as a last resort to keep bromine contamination to a minimum. Glass was mixed with cellulose and pressed into pellets for X-ray fluorescence analysis. USGS standards G-2 and GSP-1 were used, and results were corrected for absorption. Glass shards from tuff and pumice samples were analysed by electron microprobe for seven elements and were corrected for matrix effects<sup>18</sup>.

## Results: tuff correlations and ages

Three tuffs stand out as having identical chemical properties and are thus considered to be the same tuff. Figure 2 summarises the chemical data for the Chari, Karari and KBS Tuffs from the Koobi Fora Formation and Tuffs H2, H4 and L from the Shungura Formation.

**Chari–Karari–L:** the Chari and Karari tuffs of the Koobi Fora Formation cap their respective sections at Ileret and along the Karari Ridge. These two tuffs have been thought to be correlative on the basis of stratigraphic position<sup>7</sup>, K–Ar dates<sup>10</sup> and similar faunas in the underlying strata<sup>9</sup>. Trace and minor element contents of glass from pumice confirm this presumed correlation (Fig. 2). Electron microprobe analyses of individual shards from tuffs and of glass from pumice show that both have the same composition. One pumice cobble from Tuff L of the Shungura Formation has the same major, minor and trace element composition as pumice from the Chari and Karari Tuffs (Fig. 2, Tables 1, 2). A glass separate from Tuff L is nearly identical in trace element chemistry to that of the pumice (A. Martz, personal communication). Feldspars from pumice in the

Chari and Karari Tuffs and from Tuff L range in composition from about  $An_{10}Ab_{28}Or_{12}$  to  $Ab_{64}Or_{36}$ . Average calcium, iron and barium contents in these feldspars over the compositional range  $Or_{32}–Or_{36}$  are given in Table 3. The compositional range over which the average was taken is restricted because both barium and iron vary systematically with composition of the feldspar, and also to ensure comparability between different data sets on feldspars with different compositional ranges. K–Ar dating on nine feldspar separates range from 1.26 to 1.48 Myr and average about 1.35 Myr (R.E.D., in preparation). This agrees with previous results<sup>10</sup>.

As these tuffs have identical ages (R.E.D., in preparation) and chemical compositions, and because their feldspars are nearly identical in composition, they are probably products of the same eruption, and represent the same time horizon even though they were deposited by different drainage systems. This may indicate that the source area is on the drainage divide separating the two areas, as postulated earlier<sup>19</sup>.

Present nomenclature is confusing; the name 'Karari Tuff' should be eliminated as the name 'Chari Tuff' has precedence. Because both the terms 'Chari Tuff' and 'Tuff L' are firmly entrenched in the literature, however, we propose to use each term in its respective section.

**KBS-H2:** nine pumice fragments from the KBS Tuff in area 131, two pumice fragments from near the KBS type locality in area 105, and two pumice fragments from Tuff H2 were analysed (Fig. 2). Three distinctive pumice types are found in area 131: very dark brown glass with large vesicles containing about 5.5%  $Fe_2O_3$  (one sample); grey glass with moderate vesicles having about 4.2%  $Fe_2O_3$  (three samples); and silky white glass with stretched tubules having about 3.1%  $Fe_2O_3$  (five samples). This tuff consists of platy and stretched glass

Determinations are by electron microprobe unless otherwise specified. Total iron as Fe<sub>2</sub>O<sub>3</sub>.

\*Analysis by X-ray fluorescence.

shards; generally about 30% of these are brown to dark brown and close examination shows that there is a continuum from the colourless to the dark shards. Locally, basal portions of the tuff lack the dark shards. Electron microprobe studies show no difference in chemical composition between light and dark shards and indicate that they both have the same composition as the most common pumice type (that with about 3.1% Fe<sub>2</sub>O<sub>3</sub>, see Table 1). The three types are easily distinguished on the basis of their trace element chemistry (Table 2, Fig. 2). K-Ar dates were determined on all three types of pumice to determine whether older pumice had been reworked into a younger tuff. If this is the case, the pumices involved must differ in age by less than the analytical error (about  $\pm 0.03$  Myr), as the groups had average

dates of 1.82, 1.83, and 1.84 Myr, respectively (R.E.D., in preparation). Concordant glass-feldspar pairs were found for two pumice (R.E.D., in preparation).

Two pumice from the type KBS Tuff in area 105 have the same composition as the dominant group in area 131; electron microprobe analyses on glass shards from the tuff show that it is the same tuff as in area 131 (Table 1). A conventional K-Ar date of 1.75 Myr was obtained for one feldspar separate (R.E.D., in preparation). Two pumices from Tuff H2 in the Shungura Formation also have the same composition as the dominant pumice type in area 131 (Fig. 2). Electron microprobe analyses of glass from the pumice confirm this conclusion (Table 1). Four conventional K-Ar analyses (three from samples not analysed

†Analysis taken from ref. 5.

by X-ray fluorescence and from an earlier study<sup>5</sup>) average 1.87 Myr (R.E.D., in preparation).

There are several types of feldspars from the KBS Tuff. Those from pumice samples, where the iron content of the glass is about 3.1 or 4.2%, are indistinguishable chemically, and range from about An<sub>8</sub>Ab<sub>76</sub>Or<sub>16</sub> to Ab<sub>62</sub>Or<sub>38</sub>. Those from samples, where the iron content of the glass is about 5.5%, range from about An<sub>16</sub>Ab<sub>73</sub>Or<sub>10</sub> to Ab<sub>63</sub>Or<sub>37</sub> and are distinctly higher in calcium and barium. Averages for all points with greater than 32% Or are given in Table 3. These feldspars are clearly distinct from the feldspars of the Chari-L Tuff. A third feldspar type is found in the KBS Tuff from area 105-E; it is distinct from the other two and is discussed below.

## Discussion

The combined evidence justifies a correlation between the KBS Tuff of the Koobi Fora Formation in areas 131 and 105 and Tuff H2 of the Shungura Formation because of the close correspondence in age (R.E.D., in preparation) and composition. The age of 1.8 Myr for this tuff (R.E.D., in preparation) is compatible with palaeomagnetic studies<sup>20</sup>, which place this tuff in a normally polarised section, and with faunal evidence<sup>9</sup>. We propose that this ash should continue to be called by its original term to avoid confusion in future studies.

KBS (area 105-East)-H4: the tuff that occurs in area 105-East is not the KBS Tuff because no pumice characteristic of that found in the KBS Tuff in areas 105 and 131 are found in this area. Compositions of glasses from pumice show that they are members of an alkaline-rhyolite differentiation series (Fig. 2, Table 2). A single pumice lump from Tuff H4 of the Shungura

Formation also falls on this differentiation trend. Composition of minor element chemistry of feldspars from pumice also show them to be related (Table 3, samples 77-50A and H4). Conventional K–Ar dates on these samples average 1.8 Myr. Although this tuff is similar in age to the KBS Tuff and Tuff H2, and also occurs in normally polarised sediments, stratigraphic relationships in the Shungura Formation show that Tuff H4 occurs about 15 m above Tuff H2<sup>21</sup>; this tuff is therefore younger than Tuff H2. Because these pumice from the KBS Tuff in area 105-East and Tuff H4 have indistinguishable chemistries, feldspar compositions, and conventional K–Ar dates (R.E.D., in preparation) they are probably the same tuff.

Correlation of the Chari and Karari Tuffs with Tuff L, of the type KBS Tuff with Tuff H2, and of the tuff in area 105-East with Tuff H4 of the Shungura Formation is independent of the controversy surrounding the age of the KBS Tuff<sup>9–14</sup>. However, the correlations presented here are compatible with palaeomagnetic studies<sup>20,21</sup> and additional K–Ar dates on other tuffs within the Koobi Fora, Kubi Algi and Shungura Formations<sup>5</sup>.

# Application of 'molecular' theories to the structure of the crystalline state

Jeremy K. Burdett

Chemistry Department, University of Chicago, Chicago, Illinois 60637

*Recent years have seen the development of simple molecular orbital based ideas to view the structures of molecular ring, cage and cluster compounds. The principles of these methods are used here to demonstrate in a new way how the structures of solids depend on electronic configuration.*

IN contrast to the structures of simple molecules there are many possibilities for the geometrical arrangement of simple systems as extended arrays in solids. We may pinpoint three general factors which determine a solid state structure. First, the efficient packing together of the atoms in the solid. The occurrence of a particular AX structure will often be restricted if the radius ratio

of the two atomic species A and X is unfavourable. Second, the preservation of long-range order. Many structures look very favourable when a small cluster of atoms is built up but sometimes completion of another coordination shell is not possible whilst retaining the symmetry of the structure. Third, electronic forces. These may be divided into ionic, non-directional effects and covalent forces, directional in character. This article shows how recent developments in understanding the structures of molecular ring, cage, and cluster species may be used to provide a new way of viewing the structures of solids.

### Theories for molecular species

One way, due to Mingos<sup>1</sup>, that we can look at the geometries of these cages and rings is to start by taking the molecular orbital structure of a simple symmetric system and inquire what happens to the number of skeletal bonds as we add electrons to the system. Figure 1 shows a molecular orbital diagram for a tetrahedral  $A_4$  species. It is characterised by the fact that there are six low energy orbitals holding the framework together and to higher energy six orbitals which are antibonding between the A atoms. The four orbitals which point outwards from the tetrahedron and do not take part in framework bonding are not shown. With five electrons per A atom there are just enough to fill all the six skeletal bonding orbitals (number of skeletal electron pairs,  $n = 6$ ) and the outward pointing orbitals (lone pairs). This is the case for the electron precise tetrahedral molecule  $P_4$  (Fig. 1) where there are six P-P linkages. For  $n = 7$  two electrons must go into an antibonding orbital and one of the AA bonds is broken. Thus the structure found for  $B_4H_{10}$  is an opened-out tetrahedron. With  $n = 8$  a similar structure results for  $P_4(cy)_4$  (cy = cyclohexyl) but with no central linkage. For  $n = 9$  three of the tetrahedral bonds must be broken. This is a novel way of looking at  $PCl_3$  or  $S_2F_2$ . The presence of a central atom does not disturb this simple picture (but we must be careful to count the number of skeletal electrons properly) and with 12 'skeletal' pairs  $CCl_4$  has no bonds between the A (in this case Cl) atoms. An analogous scheme holds for the rationalisation of the structures of many transition metal cluster complexes which are difficult to understand in more conventional ways.

**Fig. 1** a, Schematic molecular orbital picture of a tetrahedral  $A_4$  species; b, the structures of some four atom units; c, the latter viewed using Wade's scheme.

The second approach, due to Wade<sup>2,3</sup>, is again based on the number of skeletal electrons in the molecule,  $n$ . The resultant structure is based on that of an  $N$  vertex deltahedron where  $N = n - 1$ . If the carborane or cage compound has  $N$  skeletal atoms then all the vertices will be occupied (a *closo* structure) if  $N - 1$  atoms all the vertices but one will be occupied (a *nido* structure), if  $N - 2$  atoms then all the vertices but two will be occupied (an *arachno* structure), if  $N - 3$  atoms then all the vertices but three will be occupied (a *hypho* structure), and so on. Figure 1 also shows how the  $P_4$ ,  $B_4H_{10}$  and  $P_4cy_4$  molecules are viewed on this scheme, as *nido*, *arachno* and *hypho* species. Various rules<sup>4</sup> have been developed to predict which vertices will be left vacant in *nido*, *arachno* and *hypho* structures.

### Bond breaking and the number of valence electrons

A large number of AX systems with eight valence electrons per formula unit adopt the zincblende (sphalerite) or wurtzite structure (Fig. 2.) ZnS, carbon (diamond), AlSb, CuCl, CuBr, HgS are among the systems which adopt the former structure and

**Fig. 2** a, The zincblende (sphalerite) and b, wurtzite structures; c, part of the zincblende structure indicating a 'unit cage'; d, unit cage of the wurtzite structure (other ways of choosing the cage are, of course, possible).

ZnO, AlN, BeO, CdS, CuI, MgTe the latter. Some of the examples are dimorphic. (For details of these and other systems cited here see refs 5-7.) Extraction of a chunk of lattice from each structure reveals the basic building block and demonstrates the similarity between the two systems. We recognise in these two lattice fragments the framework found for adamantane or  $P_4O_6$  and  $P_4O_{10}$  (zincblende) or bicyclo(222)octane or barrelene (wurtzite) in molecular systems. How the molecule (or solid) is held together is best illustrated for the case of the diamond configuration. Each carbon atom has four, equivalent, tetrahedrally directed orbitals on a localised equivalent molecular orbital picture, made by suitable combination of 2s and 2p orbitals. With four electrons, each carbon atom contributes half a bonding electron pair to either a cage bond (that is towards the framework of the structures of Fig. 2c, d) or to an outward pointing bond which connects this cage to another. Thus no electrons go into antibonding orbitals and there are the right

number of electrons to make four bonds around each carbon atom. In the case of molecular  $P_4O_6$  the outward pointing orbitals are filled with lone pairs of electrons leaving just 24 electrons, (that is 12 pairs) to make all 12 intracage bonds. These are examples of electron precise structures and regular geometries are found. But what happens when more than eight electrons per atom pair are present? According to the approach above, bonds are broken. Equation 1 shows one series of structures we will follow which show that the 'molecular' approach also works well for solids.

Wurtzite:	$ZnS \rightarrow \beta GaSe \rightarrow As \rightarrow Se, Te \rightarrow I_2 \rightarrow Xe$	1
No. of electrons:	8    9    10    12    14    16	

We start by considering the wurtzite structure. Each cage (Fig. 2d) contains two formula units. The three AX units forming the sides of the prism are shared by three such cages, the 'apical' AX unit is associated with only one cage. The apical atoms are attached to another cage by a single linkage top and bottom. The prismatic atoms are each attached to two other cages. There are thus 16 electrons per cage, all residing in bonding orbitals. With one extra electron per formula unit (for example GaSe) there are sufficient electrons to break one two-electron-bond per cage. We need to count up the number and type of the bonds present in the cage very carefully in order to see how many bonds may be broken. We may break either two extra-cage linkages, (a) in Fig. 2d, three prismatic cage linkages (b) or two pyramidal (c) linkages with these electrons. If extra-cage bonds are broken

then each cage will contribute to the bond breaking, and two of these bonds may be broken for each pair of electrons contributed by a single cage. If cage bonds themselves are broken, the number which may be broken per extra electron pair per cage depends on the number of cages that share a particular linkage: three for the prismatic bonds, b, and two for the pyramidal bonds, c. The structure of  $\beta$ -GaSe (Fig. 3a) shows that the bonds broken are either both the a bonds or all three b bonds, the result being indistinguishable because of the symmetry of the structure. It is important that the number and type of linkages broken compared to the wurtzite structure accords with the number of extra electrons present. Two other differences are of note by comparison with the wurtzite geometry. First, after bond fission, each of the layers moves with respect to the one beneath it. This clearly aids the packing together of the layers. Second, a readjustment of the atom positions within the cage has occurred. The Se atoms only occupy the apical positions of the wurtzite cage fragment. GaTe has a related structure with the Te atoms in the apical sites but with some other differences.

A structure where different linkages of the wurtzite cage are broken is that of wolfsbergite  $CuSbS_2$ . If we write this as  $Cu(I)Sb(III)S_2$  to satisfy divalent sulphur then the copper contributes one 4s electron to the electron count. Antimony contributes five electrons and this leads on average to nine electrons per AS unit that is one more than in  $ZnS$  and makes this structure iso-electronic with GaSe. Wolfsbergite is a superstructure of wurtzite and we can readily see from Fig. 3b that two pyramidal SbS linkages are broken.

Again the sites of lowest coordination, where the breakage has occurred contain the most electronegative species. This observation accords with a general feature of molecular cage compounds. The sites of lowest coordination are invariably those carrying the highest charge. Just as in discussions<sup>8</sup> of the forces determining ligand site preferences in molecular compounds the most electronegative ligand will prefer the sites of highest electron density. We do not know at present why wolfsbergite and  $\beta$ -GaSe have different structures. In enargite  $Cu_3AsS_4$  ( $Cu(I)Cu_2(II)As(III)S_4$ ) there is half an electron on average per AS formula unit. This is enough to break only one extra cage bond of the wurtzite unit but is insufficient to produce a separation between two halves of the structure as in  $CuSbS_2$  or GaSe (we need to break two bonds at least) and the result is a distorted structure based on wurtzite, in which the atoms are displaced from their ideal positions. Instead of regular tetrahedral coordination a range of Cu-S and As-S bond lengths are found. If the structure is regarded as being made up of  $Cu_3(I)As(V)S_4$  then the structure is an electron precise one (four electrons on average per AS formula unit) and an undistorted tetrahedral superstructure is expected.

With 10 electrons per formula unit there are now sufficient extra electrons to break two bonds per cage. In addition to the two extra-cage linkages broken in GaSe, the three vertical linkages, b, may also be broken. (Note that each vertical cage linkage is shared by three cages, so that one extra pair of electrons contributed per cage is sufficient for fission of all three.) The As structure is just this and again the layers are moved with respect to each other to aid in packing (Fig. 4a). With 12 electrons one more bond may be broken per cage and the result is the chain structure (Fig. 4b) found for elemental Se or Te. With 14 electrons another bond may be broken and the result is a lattice composed of molecular  $I_2$  units, still retaining (Fig. 5) in fact a geometrical resemblance by packing of the diatomic units, to the parent structures. The almost trivial case of Xe with 16 electrons has no bonds between the atoms and a van der Waals solid results.

Another of the systems that we could have considered (which we will examine in more detail elsewhere) starts with the eight electron rocksalt (NaCl) structure and observes the gradual breaking of bonds as more electrons are added. Thus the layer structures of arsenic and black phosphorus with two extra electrons built from three coordinate atoms are neatly viewed as arising through two different bond-breaking patterns of the

Fig. 3 a, The  $\beta$ -GaSe structure; b, the wolfsbergite ( $CuSbS_2$ ) structure. Large circles Se, small circles Ga or Cu, and small full circles, Sb.

Fig. 4 a, The As layer structure; b, the chain Se, Te structure.

rocksalt structure. TlF and InCl also with two extra electrons have distorted rocksalt-structures where in the latter for example the chlorine atoms are coordinated by three In atoms at 2.91 Å and three at 3.51 Å. InS, with only one extra electron has a structure halfway between that of NaCl and black phosphorus, is a geometry difficult perhaps to understand any other way. Complex sulphur-containing minerals with a non-integral number of electrons per formula unit are also approachable using our scheme. Thus marrite  $\text{PbAgAsS}_3$  contains on average 9.33 electrons per AS atom pair. The structure of this mineral is a distorted superstructure of rocksalt containing six coordinate lead, three coordinate arsenic and three different sulphur environments. Two are four coordinate and one is five coordinate. On average then per atom pair  $1\frac{2}{3}$  'bonds' of the rocksalt structure are broken; close to what would be predicted by interpolation between the results for eight and 10 electron structures. These ideas could be useful as a way to rationalise complex sulphide and sulphosalt structures in general. A similar analysis applies to silicate structures.  $\text{SiO}_2$  itself exists in several modifications, the  $\beta$ -cristobalite and tridymite arrangements being closely related (via an oxygen atom spacer) to those of zincblende and wurtzite. It is also found, with  $\text{Al}^{3+}$  substituted for Si and a cation present to maintain electrical neutrality, as feldspars and zeolites which are also three dimensional networks. ( $\text{SiO}_2$  has 5.33 electrons per atom.) With 5.71 electrons per atom ( $(\text{Si}_2\text{O}_5)^{2n-}$  units are found which give rise to double chains (such as gillespite) and sheet structures (such as micas). With 5.87 electrons per atom ( $(\text{Si}_4\text{O}_{11})^{6n-}$  is reached, and

double chains (such as amphiboles) are found. With 6.00 electrons, the structure is broken up further ( $(\text{SiO}_3)^{2n-}$ ) and linear or cyclic single chains are found as in benitoite and the pyroxenes respectively. With 6.4 electrons per atom isolated  $\text{SiO}_4^{4-}$  tetrahedra are found as in the orthosilicates such as the olivines. This neatly shows that the electron rich species are made up of increasingly smaller units.

Fig. 5 The  $\text{I}_2$  unit cell. The dashed lines show the similarity to the Se, Te spirals of Fig. 4b.

Extra electrons may be introduced in other ways such as inclusion of an alkali or alkaline earth metal into the structure. Thus  $\text{CaSi}_2$  (10 electrons per  $\text{Si}_2$  unit) has a rumpled sheet structure just like As, and  $\text{CaSi}$  (12 electrons per  $\text{Si}_2$  unit) has zigzag chains just like Se or Te.

Thus, whereas it has been known for a long time that iso-electronic species often have very similar crystal structures we have shown here how the structure adopted may be simply derived. It would be an important step in the classification of the crystalline state if we could relate in general the structure of a particular solid to a reference geometry by consideration of its electronic configuration. We anticipate that this would only work in those systems where covalent or directional forces are important.

### Electron counting schemes

A survey of solid state structures based on the zincblende ZnS structure immediately shows some similarities to Wade's molecular scheme. The  $\text{CdIn}_2\text{Se}_4$  and  $\text{CdAl}_2\text{S}_4$  species crystallise as defect zincblende structures. (Fig. 6). We may represent them as  $\text{Cd}\square\text{In}_2\text{Se}_4$  and  $\text{Cd}\square\text{Al}_2\text{S}_4$  where  $\square$  = vacancy to emphasise their stoichiometric relationship to ZnS. On average per AS or ASe unit ( $A = \text{Cd}, \text{In}, \text{Al}$  or  $\square$ ) there are eight electrons, just as in ZnS and an average of 12 electrons per 'zincblende' cage. This cage structure is neatly regarded as a *nido* ZnS structure. The zincblende structure of Fig. 2 would, of course, be regarded as a *clos*o structure. Examination of a model of this system shows that there are three different zincblende 'cages'. One of these has no atoms missing, the second has two and the third has one.

Fig. 6 The defect zincblende structure of  $\text{CdIn}_2\text{Se}_4$ . Large circles Se.

So the structure contains, *closo*, *nido* and *arachno* cages. There are many other examples.

In fact solid state chemists have used electron counting ideas similar to these for many years, which we may formulate as four principles.

(1) Starting with a close packed cubic array of 'anions', filling of the various holes gives the following structures: zincblende (one tetrahedral hole),  $\text{CaF}_2$  (two tetrahedral holes),  $\text{NaCl}$  (one octahedral hole) and so on.

(2) By substituting different cations with the same or average number of electrons in an ordered fashion a superstructure may be built up.

(3) By substituting cations with more electrons per atom some of the sites of the structure remain vacant in an ordered fashion.

(4) By substituting cations with less electrons per atom filled up derivatives are obtained.

Rule (1) is the solid state analogue of the description of the deltahedra on which the molecular structures are based.

Rule (2) has no molecular analogue in the strictest sense as superstructures are essentially a solid state concept but the best

analogy is that similar structures with the same number of skeletal atoms are obtained on substitution of, for example, a BH group by an  $\text{Fe}(\text{CO})_3$  group.

Rule (3) immediately recalls the occurrence of *closo*, *nido* and *arachno* molecular species.

Rule (4) has its molecular counterpart in cluster compounds with a central atom for example,  $\text{Ru}_6(\text{CO})_{17}\text{C}$ . The analogy between the two schemes applied to molecular species and extended arrays is then very striking.

*Two large DNA fragments overlapping the chicken ovalbumin gene have been isolated by molecular cloning. Analysis of these fragments provided a map of a 46,000-base pair region of the chicken genome. This region contains the complete ovalbumin gene (including its mRNA leader-coding sequence) and at least two other genes of unknown function. All three genes are orientated in the same direction and their expression in chicken oviduct is under hormonal control. The three genes share some sequence homologies, suggesting that duplications have occurred in the ovalbumin gene region in the course of evolution.*

IN the chicken oviduct, the transcription of several genes, including ovalbumin, is strongly stimulated by steroid hormones<sup>1–4</sup>. Knowledge of the structure of these genes should help in the understanding of hormonal control and gene regulation in higher organisms. Following the discovery that the ovalbumin gene is split<sup>5,6</sup> we<sup>7–11</sup> and others<sup>12–14</sup> have analysed its organisation using various methods, including molecular cloning of chicken DNA fragments, and demonstrated the presence of seven introns (intervening sequences) in the ovalbumin gene (Fig. 1c; see ref. 15 for review). Evidence for a 47-nucleotide-long leader sequence at the 5' extremity of ovalbumin mRNA (ov-mRNA) has been obtained<sup>10,14,16</sup>. The leader-coding sequence is not present in any of the gene fragments which we had cloned previously<sup>10</sup>.

In an attempt to isolate the ov-mRNA leader-coding sequence and to characterise the surroundings of the ovalbumin gene, we decided to clone large DNA fragments overlapping the gene. We report here the isolation of two DNA fragments which cover a 46-kilobase region of the chicken genome. This region contains, in addition to the complete ovalbumin gene including its leader-coding sequence, two other genes which are both expressed in the oviduct under hormonal control, and which share some sequence homologies with the ovalbumin gene.

## Isolation of DNA fragments overlapping the ovalbumin gene

We previously<sup>7,8,11</sup> cloned four *EcoRI* chicken DNA fragments ('a', 'b', 'c' and 'd'), which carry most of the ov-mRNA coding sequences (see Fig. 1c and ref. 10). We next attempted to isolate adjacent regions by cloning, in  $\lambda$ WES (ref. 17), chicken DNA partially digested by *EcoRI* (A.G. *et al.*, unpublished). As this approach failed, we undertook to develop a new cloning system capable of propagating large pieces of DNA (F.B. *et al.*, in preparation). Before these experiments were completed, similar cloning vehicles, named 'cosmids', were described by Collins and Hohn<sup>18</sup>. Cosmids are plasmid vehicles which can be packaged *in vitro* into phage  $\lambda$  heads. In this reaction, recombinant molecules are produced in preference to parental molecules and are efficiently converted into infectious particles which can then inject their DNA into bacteria, thus giving rise to bacterial clones harbouring recombinant plasmids. As an efficient screening method was a prerequisite for the isolation of genes from complex genomes by this method, we developed an appropriate *in situ* colony hybridisation technique<sup>19</sup>.

**Fig. 1** Restriction enzyme map of the cloned pAR1 DNA. pAR1 was constructed as follows: chicken erythrocyte DNA was partially digested with *MboI* and fractionated by sedimentation in a sucrose gradient (5–40% sucrose in 10 mM Tris-HCl pH 8, 1 mM EDTA, 1 M NaCl; sedimentation for 18 h at 25,000 r.p.m. at 4°C in a SW41 Beckman rotor). Fractions were analysed by agarose gel electrophoresis and those containing fragments of 15 to 25 kilobases were pooled. DNA was concentrated by ethanol precipitation and 5 µg were ligated to an equimolar amount of pJC74Km DNA digested by *BamHI* as previously described<sup>7</sup>. (We constructed pJC74Km by *in vitro* recombination of *EcoRI* linearised pJC74 (ref. 20) with a 7-kilobase *EcoRI* fragment of pML2 (ref. 21) containing a kanamycin resistance gene.) *In vitro* packaging<sup>18</sup> yielded 250,000 recombinants. After infection of *E. coli* strain 1,400 (ref. 19) bacteria were spread on kanamycin plates and screened by *in situ* colony hybridisation with an ovalbumin-specific <sup>32</sup>P-labelled probe (*XbaI*-*HindIII* probe, shown in line *d*, and derived from cloned ovalbumin *EcoRI* fragment 'b'). A total of 25,000 colonies was examined and one positive clone was obtained. pAR1 plasmid was re-isolated three times. A restriction map of pAR1 was constructed by analysing restriction enzyme digests of pAR1 DNA: *a*, Linear map of pAR1 showing the 17-kilobase *MboI* chicken DNA fragment integrated in the *BamHI* site of pJC74Km; *b*, Enlargement of the 17-kilobase chicken DNA fragment, showing the restriction sites for *BamHI* (▲), *EcoRI* (■), *KpnI* (●) and *XbaI* (×); *c*, Map of the ovalbumin gene<sup>10,16</sup> showing the introns (identified by letters A–G), the exons (numbered 1–7) and the leader-coding sequence (L). The boundaries of *EcoRI* fragments 'a', 'b', 'c' and 'd' are indicated above the line; *d*, Region corresponding to the ovalbumin-specific probe *XbaI*-*HindIII*. Also shown are the direction of transcription and a scale for lines *b* and *c*.

**Fig. 2** Restriction enzyme map of the cloned pAR2 DNA. Recombinants were constructed as described in Fig. 1, except that chicken DNA was partially digested with *EcoRI*, and that fragments of more than 25 kilobases (25 µg) were pooled and recombined *in vitro* with 15 µg of *EcoRI*-linearised pJC74 in a final volume of 140 µl. 2 µg of recombinant DNA were packaged *in vitro*. After infection of strain 1,400 and spreading on ampicillin plates, 20,000 colonies were screened with the *XbaI*-*HindIII* probe (see Fig. 1). One positive clone was obtained. Its restriction map was derived from a series of digests performed on whole pAR2 DNA or isolated (subcloned) fragments. It was completed by the identification of fragments which hybridise with an *XEco10* probe (see below and text) or the ovalbumin probe *XbaI*-*HindIII* (see Fig. 1). *a*, Map of pAR2 DNA linearised with *SalI*, showing the location of the 30-kilobase insert within the vector sequences. The sizes (in kilobases) of the vector or chicken DNA fragments are indicated above the line. *b*, Map of the *BamHI* (▲), *EcoRI* (■), *HpaII* (◇), *KpnI* (●) and *XbaI* (×) sites in the cloned fragment. *c*, *d* and *e*, maps of the cellular DNA fragments detected in the Southern transfer experiment described in Fig. 3 with either probe I (---) or probe II (—) (see Fig. 3). Digestion by *EcoRI* (*c*), *KpnI* (*d*) or *XbaI* (*e*). The size (in kilobases) is indicated above each fragment. *f*, Probes used for comparison of pAR2 to cellular DNA (Fig. 3): Probe I corresponds to a mixture of the 4.5-kilobase *PstI* and the 3.2-kilobase *EcoRI* fragments in the ovalbumin leader region, isolated from AC4-ov5 (ref. 16). Probe II corresponds to a 14-kilobase long *HhaI* fragment of pAR2 which was subcloned by blunt end ligation into pBR322. *g*, Location of the ovalbumin *EcoRI* fragment 'b' and of the cloned 10.5 kilobase *EcoRI* fragment *XEco10*. This fragment, which was cloned independently in *λ*WES, was selected after hybridisation with the ovalbumin *HhaI* probe<sup>8</sup> and will be described elsewhere (J.L.M. *et al.*, in preparation). The scale (for lines *b*–*g*) is given in line *c* in kilobases.

Two cosmids were used: pJC74 (from J. Collins) which can accept foreign DNA fragments of up to 32 kilobases<sup>20</sup> and pJ74Km, a kanamycin-resistant derivative which we constructed (see Fig. 1 legend) and which can accept DNA fragments of up to 25 kilobases. Chicken erythrocyte DNA, partially digested by *Mbo*I and sized on a sucrose gradient, was ligated to pJC74Km DNA made linear using *Bam*HI. *Bam*HI and *Mbo*I have identical cohesive ends which allow their ligation. In other experiments, chicken erythrocyte DNA, partially digested by *Eco*RI, was sized on sucrose gradients, and recombined with *Eco*RI-linearised pJC74 DNA. After *in vitro* packaging, infection of *recA*<sup>-</sup> strain 1400 (ref. 19), and screening by *in situ* hybridisation with a <sup>32</sup>P-labelled probe corresponding to part of ovalbumin *Eco*RI fragment 'b' (see Fig. 1d), we isolated two clones, from which the recombinant plasmids pAR1 (derived from pJC74Km) and pAR2 (derived from pJC74) were purified.

### The cloned sequences cover 46 kilobases in the region of the ovalbumin gene

Several restriction enzymes were used to construct the maps of pAR1 and pAR2 shown in Figs 1 and 2. Digestion of pAR1 DNA by *Eco*RI yielded eight fragments, including a 9.2-kilobase and a 1.3-kilobase fragment, which co-migrated with the cloned *Eco*RI fragments 'a' and 'd' of the ovalbumin gene<sup>7,11</sup> (see Fig. 1b, c). The part of the map containing these two fragments confirmed our previous data on the ovalbumin gene organisation<sup>5,7-11</sup>. There was no fragment of the size of *Eco*RI fragment 'b', but restriction mapping indicated that about half of its sequence was present, as expected as pAR1 was isolated using a probe corresponding to that region. This was further demonstrated by hybridisation of pAR1 DNA with ov-mRNA. Under the electron microscope (not shown), DNA loops corresponding to introns D, E, F and G were observed, in addition to a non-hybridised RNA tail corresponding to exons 1 and 2. From these experiments we conclude that pAR1 contains about 17 kilobases of chicken DNA, starting from the *Mbo*I site located within intron C (refs 8, 10), and ending 12.5 kilobases downstream from the 3' end of the ov-mRNA coding sequence (Fig. 1).

Digestion of pAR2 DNA by *Eco*RI yielded a series of fragments among which the ovalbumin *Eco*RI fragment 'b' (which contains exons 1 to 4) could be identified in a Southern transfer experiment<sup>22</sup> using an ovalbumin double-stranded cDNA probe (*Hha*ov, see refs 5, 23), while fragments 'a', 'c' and 'd' (which contain exons 5, 6 and 7) could not be detected (not shown). Unexpectedly, a 3.5-kilobase *Eco*RI fragment and a 2.4-kilobase *Bam*HI fragment, which were not predicted from the ovalbumin gene map, also reacted with the *Hha*ov probe (see below and Fig. 6). Similar *Eco*RI and *Bam*HI fragments which cross-hybridise with the *Hha*ov probe, but do not belong to the ovalbumin gene, have been detected previously in cellular DNA<sup>9</sup>. This suggests that pAR2 contains some of these ovalbumin-related sequences. The restriction map in Fig. 2 (a and b) indicates that pAR2 contains about 30 kilobases of chicken DNA located on the 5' side (with respect to transcription) of the ovalbumin gene (see Figs 1c, 2g and ref. 16). As will be shown below, there are sequence homologies between the ovalbumin gene region which is on the 3' side of fragment *Eco* 'b' and two other genes, X and Y, which are present in pAR2.

In view of the large size of the DNA fragment which was integrated into pAR2 and because it is the first example of the use of cosmids for cloning eukaryotic DNA, it was important to demonstrate that this cloned fragment exists as such in genomic DNA. We have compared the hybridisation patterns of restriction enzyme digests of pAR2 and chicken oviduct DNA in Southern transfer experiments. Two probes were used for hybridisation (Fig. 2f, g). Probe I covers 6 kilobases in the ovalbumin *Eco*RI fragment 'b' region. Probe II covers 14 kilobases in the middle of the cloned DNA. As shown in Fig. 3, the hybridisation patterns of pAR2 and oviduct DNAs with probe I

are identical in digests made with *Eco*RI (lanes 2 and 6) or *Kpn*I (lanes 4 and 8), or in double digests made with *Eco*RI and either *Bam*HI (lanes 1 and 5) or *Kpn*I (lanes 3 and 7). There are two *Xba*I fragments of similar size in pAR2 and oviduct DNA which hybridise to probe II (lanes 10 and 12). This probe also reacts with three fragments in *Kpn*I digests of both DNAs (lanes 9 and 11). Two of these fragments (bands b and c) have similar sizes in pAR2 and oviduct DNAs. In pAR2, a third fragment of about 26 kilobases which contains 16 kilobases of vector sequences is observed (band a, lane 11), while the corresponding fragment in cellular DNA has a size of about 18 kilobases and contains an

**Fig. 3** Restriction enzyme mapping of cloned pAR2 DNA and of the corresponding chromosomal DNA region. pAR2 DNA or oviduct DNA were digested with various restriction nucleases and electrophoresed in 0.7% agarose gels (10 µg of cellular DNA or 10 ng of pAR2 DNA per slot). Transfer on to nitrocellulose filters, hybridisation conditions and autoradiography were as previously described<sup>22</sup>. Digestions which were to be analysed with the same probe were all electrophoresed on the same gel, but cellular DNA and pAR2 DNA slots were transferred on to separate filters. Hybridisation of oviduct DNA (lanes 1-4) or pAR2 DNA (lanes 5-8) with nick-translated probe I (see Fig. 2). Fragment sizes are given in kilobases. Lanes 1 and 5: digestion with *Bam*HI and *Eco*RI, a = 7.9, b = 2.4, c = 0.5. Lanes 2 and 6: digestion with *Eco*RI, a = 14, b = 2.4, c = 0.5. (The band above fragment 'b' which appears in lanes 1 and 2 is an artefact.) Lanes 3 and 7: digestion with *Eco*RI and *Kpn*I, a = 7.2, b = 2.2, c = 0.5. Lanes 4 and 8: digestion with *Kpn*I, a = 10.5. Hybridisation of oviduct DNA (lanes 9 and 10) or pAR2 DNA (lanes 11 and 12) with nick-translated probe II (see Fig. 2). Lanes 9 and 11: digest with *Kpn*I, a (lane 9) = 18, a (lane 11) = 26, b = 10.5, c = 7.6. Lanes 10 and 12: digest with *Xba*I, a = 8.6, b = 5.1, c = 4.4. Band b (lane 12) corresponds to the *Xba*I fragment adjacent to fragment 'c' (at its left, see Fig. 2b, e). As fragment 'b' hybridises only to a very small portion of probe II, it was not detected in the cellular DNA.

additional 8-kilobase segment not present in pAR2 (band a, lane 9). As shown in Fig. 2c, d and e, the fragments hybridising to probes I and II and which are common to oviduct and pAR2 DNA, cover a 24-kilobase segment. In addition, the 10.5-kilobase region of the cloned DNA which is distal to the ovalbumin sequence, and which overlaps this 24-kilobase segment, has been found to be identical to an independently cloned chicken DNA fragment XEco10 (see Fig. 2g) which has been studied separately (J.L.M. *et al.*, in preparation). From all these results we conclude that the entire 30-kilobase region cloned in pAR2 corresponds to a single continuous segment of cellular DNA, which has not suffered any major rearrangement during cloning.

## pAR2 contains the ovalbumin leader-coding sequence

As pAR2 contains a very large segment of DNA on the 5' side of the ovalbumin gene, we expected that it should have the ov-mRNA leader-coding sequence<sup>10</sup>. We have analysed by electron microscopy the hybrid molecules formed between ovalbumin mRNA and heat-denatured pAR2 DNA, previously linearised by *SalI* (Fig. 4d). ov-mRNA hybridises over  $620 \pm 67$  nucleotides in five regions separated by four single-stranded DNA loops. Three of these loops have sizes and locations corresponding to introns B, C and D of the ovalbumin gene which allows the orientation of the molecule with respect to transcription<sup>8,9</sup>. The fourth DNA loop which is at the 5' end of ov-mRNA is  $1,606 \pm 150$  nucleotides long (Fig. 4d). This loop corresponds to intron A, which was expected to separate exon 1 from the sequence coding for the mRNA leader<sup>10</sup>. Indeed both the length of loop A and the location of several restriction sites in the corresponding region of pAR2 agree with data obtained on two other independently isolated clones where the presence of the leader-coding sequence at the 5' end of the loop was unequivocally demonstrated by DNA sequencing<sup>16</sup>. The free mRNA tail, which is about 1,200 nucleotides long, corresponds to exons 5, 6 and 7 which are not present in pAR2.

## pAR2 contains two other genes expressed in oviduct of laying hen

In the 46-kilobase DNA region cloned in pAR1 and pAR2, the ovalbumin gene occupies only about 7.7 kilobases<sup>16</sup>. This could leave ample space for other genes. As we were interested to know whether genes which share a similar hormonal regulation of expression in chicken oviduct could be clustered, we have hybridised total poly(A) RNA from laying hen oviducts with pAR1 or pAR2 DNAs. No RNA other than ov-mRNA was found to hybridise to pAR1 DNA. In contrast, electron microscopy of the hybrid molecule revealed that, besides ov-mRNA, two other RNA molecules hybridised to the same strand of pAR2 DNA (Fig. 4a), indicating the presence of three genes transcribed in the same direction (Fig. 4a). The polarity with respect to transcription is given by the ov-mRNA-DNA hybrid region which is easily identified by the characteristic array of DNA loops corresponding to introns B, C and D (Fig. 4a, d, see below for the absence of the loop corresponding to intron A in Fig. 4a). We termed these two other genes, X and Y, giving the gene order 5'-X-Y-ovalbumin-3'.

Y RNA is  $2,020 \pm 175$  nucleotides long, as measured from the length of the DNA-RNA hybrid regions located in the middle of the cloned segment. The DNA loops indicate the presence of seven introns (A to G) in this gene, separating eight exons (1 to 8) (Figs 4c and 5a, b). Note that with Y RNA, as with ov-mRNA, the DNA loop closest to the 5' end of the RNA is not seen on all hybrid molecules (and is in fact absent for both genes in Fig. 4a). In the case of ov-mRNA this is due to the short size (47 nucleotides) of the leader sequence which does not form a very stable hybrid in the conditions used to form preferentially

DNA-RNA hybrids<sup>16</sup>. A similar situation is probably encountered with Y RNA, as its exon 1 is not actually resolved by electron microscopy and its existence is inferred from the presence of loop A (Fig. 4c). The total length of the Y gene (exons + introns) is about 6.5 kilobases, and its 3' end lies about 11.5 kilobases upstream from the ov-mRNA leader-coding sequence.

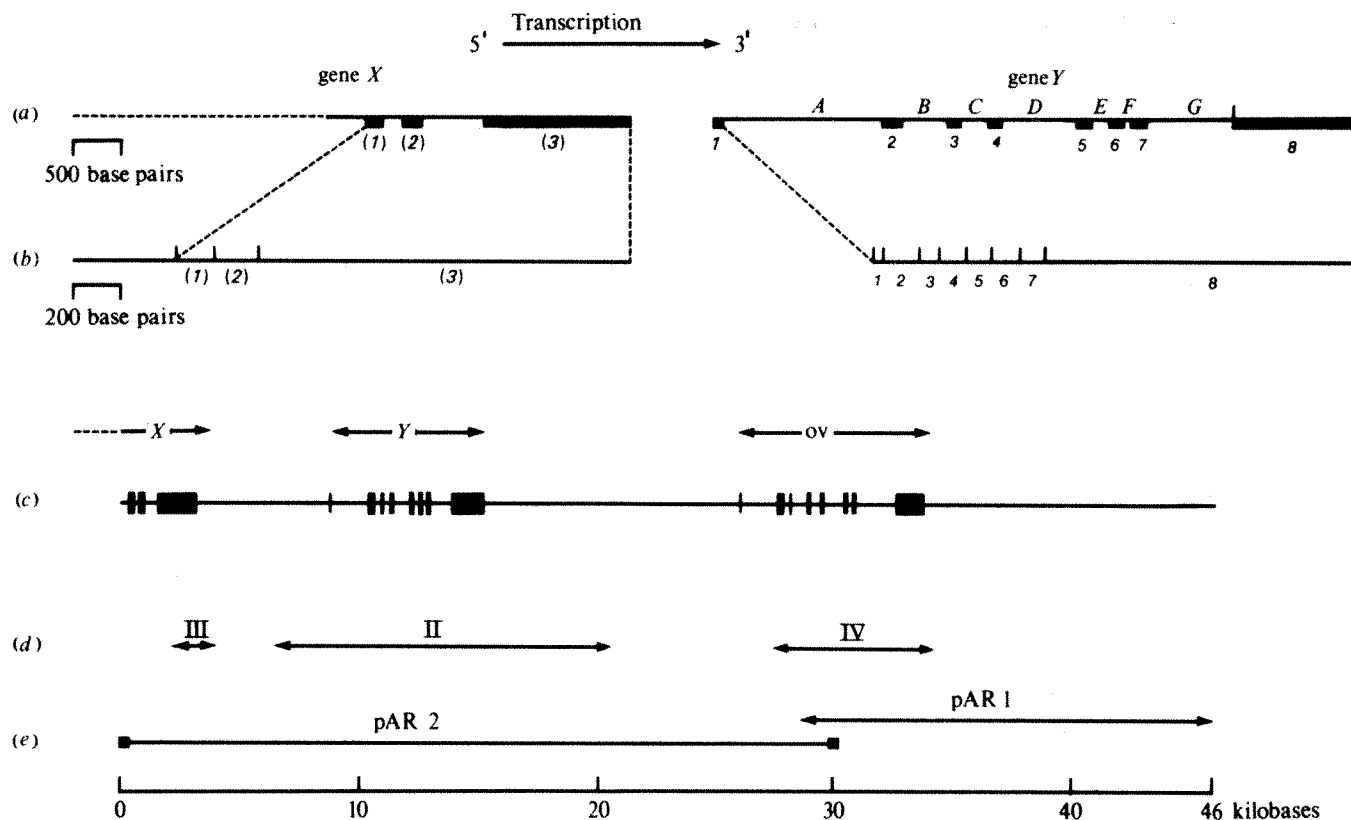

X RNA is about 2,400 nucleotides long. It hybridises to pAR2 DNA over  $1,945 \pm 200$  nucleotides in three exons separated by two DNA loops (introns) (Figs 4b and 5a, b). The presence of a free RNA tail of about 400 nucleotides indicates that the region coding for the 5' end of this RNA is not present in pAR2 DNA. There are about 5.5 kilobases between the 3' end of the X gene and the 5' end of the Y gene. Using these data, genes X and Y were positioned on the restriction enzyme map as shown in Figs 5c and 6B(I).

## X, Y and ovalbumin genes share sequence homologies

In the original mapping of pAR2 DNA (see above) we found that, in addition to the ovalbumin gene sequences, some other parts of the DNA hybridised with the ovalbumin-specific *Hha*ov probe<sup>5,23</sup>. The finding of genes X and Y prompted us to investigate whether the cross-hybridising regions could correspond to these genes.

pAR2 DNA was digested by *Hpa*II and either *Eco*RI or *Bam*HI. *Hpa*II cuts the cosmid DNA into very small fragments, facilitating further analysis of the cloned chicken DNA, which is cut only two times. Digestion of the DNA from pAR2 with *Hpa*II and *Eco*RI yields one band (band c, lane 1, Fig. 6A) which hybridises strongly with the *Hha*ov probe. Two other bands of weaker intensity (bands a and b, lane 1) were also revealed. From the restriction enzyme mapping of pAR2 we can unambiguously identify these bands and show their location in Fig. 6B, line 1. Similarly, in a *Hpa*II and *Bam*HI double digest, hybridisation with the *Hha*ov probe yielded one intense band (band a, lane 2, Fig. 6A), which includes the ovalbumin coding region and two other bands (bands b and c, lane 2), which are located in the regions of the DNA coding for genes Y and X, respectively (see Fig. 6B, line 2). These homologies were further analysed using a probe from the region of gene X (probe V, Fig. 6B, line 5). On digestion with *Hpa*II and *Eco*RI, two bands of hybridisation were obtained (lane 3, Fig. 6A): band a which includes part of gene Y, and band b which contains the region from which the probe was prepared (see Fig. 6B, line 3). Using the same probe with DNA digested by *Hpa*II and *Bam*HI, three bands of hybridisation were found (Fig. 6A, lane 4). Two of these bands (c and d) originate from gene X, whereas band b corresponds to a part of gene Y (see Fig. 6B, line 4). These experiments show that there are homologies between regions of genes X and Y, and that both genes contain sequences which are homologous to some ovalbumin exonic sequences. Even so, these three genes and their RNA transcripts are clearly different, as indicated by the electron microscopic results and by

**Fig. 4** Electron micrographs of RNA-DNA hybrid molecules between laying hen oviduct RNA purified on oligo(dT)-cellulose and pAR2 DNA. RNA-DNA hybrids were formed by incubating heat-denatured linear pAR2 DNA ( $1.5 \mu\text{g ml}^{-1}$ ) with oligo(dT)-cellulose-purified RNA ( $100 \mu\text{g ml}^{-1}$ ) at  $54.3^\circ\text{C}$  and prepared for electron microscopy<sup>7</sup>. pAR2 DNA was linearised by digestion with *SalI*. In the line drawings, the RNAs are represented as a dashed line and the DNAs as a solid line. Scale bars represent  $0.1 \mu\text{m}$ . **a**, Electron micrograph of a complete single-stranded pAR2 DNA molecule hybridised with three RNA molecules. Arrows X, Y and ov point to the respective genes. Arrow heads 5' and 3' indicate the 5' and the 3' extremities of the RNAs. The total length of pAR2 DNA is  $45,940 \pm 6,600$  base pairs (from the measurements of 20 molecules). The X RNA hybridises to a DNA sequence which lies  $10,460 \pm 1,150$  base pairs from the nearest pAR2 DNA end. There are  $5,560 \pm 600$  base pairs between the 3' end of the X gene and the 5' end of the Y gene and  $11,580 \pm 1,350$  base pairs between the 3' end of the Y gene and the 5' end of the ovalbumin gene. There are  $5,330 \pm 540$  base pairs between the DNA sequence which hybridises to ov-mRNA and the end of the molecule. Loops A of the ovalbumin gene (see Fig. 4b) and of the Y gene (see Fig. 4c) are not visible in this picture, presumably because the hybrids responsible for their presence are not very stable (see text). **b**, Electron micrograph of an X RNA-DNA hybrid molecule. The hybrid region is  $1,945 \pm 243$  base pairs long (from the measurements of 20 molecules). The free RNA tail is about 450 nucleotides long. The two single-stranded DNA loops 'a' and 'b' are  $253 \pm 47$  and  $812 \pm 120$  nucleotides long, respectively. The hybrid segments are (from 5' to 3')  $175 \pm 39$ ,  $181 \pm 35$  and  $1,613 \pm 219$  base pairs, respectively. Other symbols as under (a). **c**, Electron micrograph of a Y RNA-DNA hybrid (from the measurements of 20 molecules). The hybrid region is  $2,020 \pm 175$  base pairs. The length of the single-stranded DNA loops A to G are  $1,729 \pm 180$ ;  $492 \pm 130$ ;  $303 \pm 88$ ;  $812 \pm 135$ ;  $206 \pm 86$ ;  $55 \pm 20$  and  $890 \pm 134$  nucleotides long, respectively. The hybrid segments (from 5' to 3') are  $218 \pm 71$ ;  $93 \pm 30$ ;  $165 \pm 40$ ;  $153 \pm 33$ ;  $167 \pm 33$ ;  $183 \pm 41$  and  $1,320 \pm 148$  base pairs, respectively. Other symbols as under (a). **d**, Electron micrograph of an ovalbumin mRNA-DNA hybrid (from the measurements of 22 molecules). The hybrid region is  $620 \pm 67$  base pairs long. The free RNA tail is about 1,100 nucleotides long. Loops A to D are  $1,606 \pm 150$ ;  $204 \pm 47$ ;  $578 \pm 95$  and  $386 \pm 85$  nucleotides long. The hybrid segments are (from 5' to 3')  $213 \pm 45$ ,  $76 \pm 23$ ,  $171 \pm 33$  and  $162 \pm 46$  base pairs long. The L arrow points to the leader-coding segment which is revealed by the presence of loop A. Other symbols as under (a).

**Fig. 5** Map of the ovalbumin gene region. *a, b*, Maps of genes *X* and *Y* indicating the respective locations of introns (designated by letters), exons (heavy lines and numbers) which are also shown on the maps of the corresponding RNAs (line *b*) where they are designated by numbers (for gene *X* the numbers are in brackets as definitive numbering of exons requires knowledge of the complete structure of the gene). *c*, Map of the 46-kilobase DNA region contained in pAR1 and pAR2, showing the location of the exons (heavy lines) of *X*, *Y* and ovalbumin (*ov*) genes. *d*, Probes used for the experiment in Fig. 7. Probe II is described in Fig. 2 legend. Probe III is a 1.8-kilobase *Hind*III fragment isolated from *XEco*10 (see Fig. 2 legend). Probe IV corresponds to the ovalbumin *Eco*RI fragment 'b' and 'c' and to a part of *Eco*RI fragment 'a' (see Fig. 1c). *e*, Limits of the fragments integrated in pAR1 and pAR2 and scale (in kilobases) for lines *c*, *d* and *e*.

**Fig. 6** Sequence homologies between *X*, *Y* and ovalbumin genes. *A*, Digests of pAR2 DNA with *Eco*RI and *Hpa*II (lanes 1 and 3) or *Bam*HI and *Hpa*II (lanes 2 and 4) were electrophoresed on a 0.7% agarose gel, transferred on to nitrocellulose filters and hybridised to probes corresponding to the ovalbumin gene (*Hhaov*: lanes 1 and 2) or to gene *X* (probe V, lanes 3 and 4). The latter probe, shown in line 5 of Fig. 6B is a 2.3-kilobase *Hind*III fragment subcloned from *XEco*10 (see Fig. 2 legend). The size of the fragments are (in kilobases): lanes 1 and 3, *a* = 14, *b* = 3.4, *c* = 2.4; lanes 2 and 4, *a* = 12.5, *b* = 3.6, *c* = 2.4 and *d* = 0.9. *B*, The location of the fragments hybridising in lanes 1 to 4 of Fig. 6A are indicated in lines 1 to 4, respectively. For a given probe the continuous line shows the fragment(s) which contain(s) part or all of the sequences of the probe, whereas dashed lines indicate additional fragments which cross-hybridise with the probe. The first line (I) gives the location of *Bam*HI (▲), *Eco*RI (■) or *Hpa*II (◇) restriction sites and indicate the regions corresponding to genes *X*, *Y* and ovalbumin. The dotted line corresponds to vector sequences. Line 5: location of probe V and scale.

the lack of hybridisation of the *Y* gene with the *Xba*I–*Hind*III probe (Fig. 1d) prepared from the ovalbumin *Eco*RI fragment 'b' (not shown).

### Expression of *X* and *Y* is under hormonal control

As transcription of the ovalbumin gene is under oestrogen control, we wondered whether the expression of *X* and *Y* is regulated in a similar way. Oviduct RNA from laying hen or oestrogen-withdrawn chicken was fractionated on methyl mercuric hydroxide agarose gels, transferred and immobilised on to diazobenzoyloxymethyl paper<sup>24</sup>. The filters were hybridised with probes specific for each of the three genes.

As shown in Fig. 7, probe IV (see Fig. 5d), specific for the ovalbumin gene, hybridised with an RNA molecule about 1,900 nucleotides long, which is present in laying hen oviduct (lane 3) but cannot be detected in 'hormone-withdrawn' oviduct (lane 1), as expected for ovalbumin mRNA. Probe III (see Fig. 5d) is specific for gene *X* as it does not contain the regions which cross-hybridise with either *Y* or ovalbumin genes (J.L.M. *et al.*, in preparation). An RNA species present in laying hen (Fig. 7, lane 7), but not in 'hormone-withdrawn' oviduct (lane 6) hybridises to this probe. As expected from the above electron microscopic results, the size of this RNA is about 2,300 nucleotides. Gene *Y* is not expressed in the 'hormone-withdrawn' oviduct (Fig. 7, lane 4) as no RNA species hybridised with probe II which contains gene *Y* (see Fig. 5d). In laying hen oviduct (lane 5) we found an RNA species, about 2,000 nucleotides long, which hybridised with probe II. But we cannot state with certainty that it is RNA *Y*, because probe II also cross-reacts with ov-mRNA, which is of similar size. However, the electron microscopic results indicate unambiguously that RNA *Y* is present in the oviduct of laying hens. That the transcription of *X* and *Y* genes is oestrogen-dependent is indicated by the presence of *X* and *Y* RNAs in oviducts following administration of oestradiol to 'withdrawn' chicken (not shown). However, the results shown in Fig. 7 and the frequency of RNA-DNA hybrids observed for *X* and *Y* genes by electron microscopy suggest that the concentration of *X* and *Y* RNAs is much lower than that of ov-mRNA.

### Organisation of the chicken genome in the vicinity of the ovalbumin gene

Cloning of eukaryotic DNA fragments using cosmid vectors has not been described previously. Our experiments show that this system, in conjunction with an appropriate *in situ* hybridisation method<sup>19</sup>, can be used successfully. Available phage vectors cannot propagate more than about 20 kilobases<sup>17,25</sup>. Using pJC74 cosmid, we have cloned a 30-kilobase DNA segment of the chicken genome. Shorter cosmid vectors should permit the cloning of DNA fragments of up to 40–45 kilobases. As such large DNA fragments have a greater chance of containing repeated sequences and might be unstable during cloning, we used a *recA*<sup>–</sup> bacterial host (some phage vectors, including  $\lambda$ Charon 4A (ref. 25), would not grow on such hosts). The efficiency of the cosmid vector system is such<sup>18,20</sup> that it is possible to construct a genomic library from a few microgrammes of eukaryotic DNA. Enrichment for a particular gene sequence before cloning seems to be unnecessary and even undesirable, as it might lead one to discard fragments of unexpected interest, such as genes of related sequences.

In one clone we found two other genes (*X* and *Y*) closely linked to the ovalbumin gene. As the existence of genes *X* and *Y* was revealed by electron microscopy of hybrid molecules between total oviduct poly(A)<sup>+</sup> RNA and the cloned DNA, we would not have detected genes coding for minor species of oviduct RNAs or RNAs expressed in other tissues. Assuming that no other genes are present in the cloned DNA, the length of the intergene regions (5–10 kilobases) and of the genes themselves (6–8 kilobases), is such that there would be one gene every 10 to 15 kilobases of DNA.

**Fig. 7** Detection of *X* and *Y* RNAs in oviducts of laying hen and 'withdrawn' chicken. Female chicks aged 5 days were injected daily with 1 mg of oestradiol benzoate for a period of 10 days (primary stimulation). Hormone treatment was then stopped and 4 weeks later the magnum portion of the oviduct was removed ('withdrawn' oviduct). Total RNA from laying hen or hormone-withdrawn oviduct was prepared according to a method developed by Dr F. Rougeon (personal communication). RNA samples (20  $\mu$ g per slot) were separated by electrophoresis on 1% agarose gels containing 10 mM methyl mercury hydroxide. The RNA was then transferred to diazobenzoyloxymethyl paper which was hybridised to <sup>32</sup>P-labelled probes and washed<sup>24</sup>. Autoradiography was with a Kodirex film (Eastman Kodak) for 4 days. Lanes 1–3: hybridisation to  $2.5 \times 10^6$  d.p.m. of <sup>32</sup>P-labelled probe IV (see Fig. 5d); lanes 4 and 5: hybridisation to  $2.5 \times 10^6$  d.p.m. of <sup>32</sup>P-labelled probe II (see Figs 2f and 5d); lanes 6 and 7: hybridisation to  $4 \times 10^6$  d.p.m. of <sup>32</sup>P-labelled probe III (see Fig. 5d); lanes 1, 2, 4 and 6: 20  $\mu$ g of total oviduct RNA from 'withdrawn' chicken; in lane 2, 0.1  $\mu$ g of laying hen oviduct RNA was added; lanes 3, 5 and 7: 20  $\mu$ g of total RNA from laying hen oviducts.

As *X*, *Y* and ov-mRNAs are produced in differentiated cells, could reorganisation of the genome in this region occur during differentiation, as in the case of immunoglobulin genes? (See refs 26 and 27 and refs therein.) Our comparison of the restriction map of the erythrocyte DNA cloned in pAR2 and of either oviduct DNA (Fig. 3) or erythrocyte DNA (results not shown) indicates that there is no major rearrangement.

There are striking resemblances (Figs 4 and 5c) in the organisation of these neighbouring genes, which are transcribed from the same strand and are under oestrogen control. More than half of the RNA-coding sequences are found uninterrupted at the 3' end of all three genes. For both the ovalbumin and *Y* genes there are seven introns and the eight regions coding for the mature RNAs are very similar in size. In addition, the first intron (intron A) is about 1,600 nucleotides long in the two genes and separates a very short RNA-coding sequence from the neighbouring exon. It will be interesting to find whether exon 1 of gene *Y* is equivalent to the mRNA leader-coding sequence of the ovalbumin gene<sup>16</sup>. The above similarities and the fact that genes *X*, *Y* and ovalbumin share partial sequence homologies strongly suggest that they could have arisen by at least partial duplications from a common precursor. In our previous work (refs 7, 9; see also Fig. 1 in ref. 5) we detected a limited number of cellular DNA fragments in the chicken genome, which cross-hybridised to the *Hha*ov ovalbumin cDNA probe, but did not belong to the ovalbumin gene. Genes *X* and *Y* account for the existence of most, if not all, of these fragments (our unpublished results). The presence in the chicken genome of other genes with the same degree of homology with the ovalbumin gene is therefore unlikely.

The organisation of the ovalbumin region is reminiscent of that found for the  $\beta$ -like globin genes<sup>28,29</sup>. Genes for  $\beta$ - and  $\delta$ -globin are closely linked, transcribed from the same DNA strand, and show extensive sequence homologies in the mRNA coding sequences, with introns in identical locations. They are both expressed in the same cellular type, albeit at very different rates. It is also known that the two  $\gamma$ -globin genes are found in the same genomic region<sup>28</sup>. The available evidence for several gene families<sup>30,31</sup> suggests that the clustering of genes which are related both structurally and functionally might not be uncommon in eukaryotic genomes. In the present case, however, we do not know if the products of genes *X*, *Y* and ovalbumin are functionally related, as the former two have not yet been identified (genes *X* and *Y* do not code for conalbumin, lysozyme or ovomucoid; our unpublished results).

Could the clustering of the three genes play a part in their expression? They could participate together in a chromatin domain (see ref. 32 and refs therein) or be transcribed and controlled by oestrogens as part of one unit. In prokaryotes, it has been demonstrated that genes of related function can be clustered in operons and transcribed by a single RNA-polymerase molecule. There is no evidence at present that this occurs in eukaryotes. In our case, transcription of all three genes by the same RNA-polymerase molecule would have to be reconciled with the following facts: (1) the largest precursor RNA for ovalbumin so far detected is about 8,000 nucleotides<sup>33,34</sup>; (2) there are large differences in the levels of the three RNAs (ov-mRNA being the most abundant); and (3) the clustering of the three genes may have no other significance than reflecting the evolutionary process which gave rise to them.

Biohazards associated with the experiments described in this publication were examined previously by the French National Control Committee. The experiments were carried out in L3-B1 conditions in the nomenclature adopted by the French Committee (*Le Progrès Scientifique* No. 191, Nov/Dec 1977). We thank Dr J. Collins for providing pJC74, Dr B. Hohn for providing strains, information and advice for *in vitro* packaging, Dr P. Courvalin for pML2 DNA, and Dr F. Rougeon for T<sub>4</sub> DNA ligase and useful advice. The technical help of Mrs O. Lebail, A. Hémard, Mrs C. Kutschis, E. Sittler, M. C. Chanal, C. Wasylyk, Mr Garnier and B. Boulay is acknowledged. This work was supported by grants to P.K. from the CNRS (ERA 201,

ATP No. 3558), INSERM (CRAT 76.4.319 and 76.4.465), the DGRST and the Fondation de la Recherche Médicale Française, and by grants to P.C. from the CNRS (ATP 2117), INSERM (CRAT 76.5.462 and 76.5.468) and the Fondation pour la Recherche Médicale Française. J.P.LeP. was supported by a fellowship from the Université Louis Pasteur and A.R. is a post-doctoral fellow of the NCI of Canada. Electron microscope facilities were made available to F.P. by INSERM and CNRS.

## Histone genes are clustered with a 15-kilobase repeat in the chicken genome

R. J. Crawford, P. Krieg, R. P. Harvey, D. A. Hewish & J. R. E. Wells

Department of Biochemistry, University of Adelaide, Adelaide, South Australia 5001

*Histone mRNA isolated from 5-day-old chick embryos has been used as a template for complementary DNA (cDNA) synthesis. The resultant cDNA, after removal of sequences complementary to rRNA, was used to detect histone genes in adult chicken genomic DNA. Hybridisation data indicate that the histone genes are repeated about 10-fold in the chicken genome. Restriction endonuclease analysis reveals some sequence heterogeneity in these genes. However, the results show that chicken histone genes are clustered with a basic repeat unit of 15 kilobases.*

THE organisation of histone genes in sea urchin species has been elegantly demonstrated by mapping restriction endonuclease fragments<sup>1-3</sup> and by electron microscopy<sup>4</sup>. A prerequisite for these studies was the availability of a probe of sufficient radio-

chemical purity to allow unequivocal detection of histone gene sequences. In the sea urchin system, it was possible to take advantage of the fact that early cleavage embryos synthesise predominantly histone mRNA. Pulse-labelled RNA isolated from these cells, although contaminated with other RNA, was perfectly usable because almost all the radioactivity was contained in histone mRNA.

Histone gene sequences from the sea urchin have also been useful in studying *Drosophila* histone genes. Cross reactivity between sea urchin and *Drosophila* histone coding sequences has led to the isolation and subsequent analysis of cloned *Drosophila* histone genes<sup>5</sup>. Other systems have not been so amenable. Despite intensive efforts, isolation of histone mRNA of comparable radiochemical purity from pulse-labelled *Drosophila* tissue culture cells<sup>6</sup> or HeLa cells<sup>7</sup> has been very difficult. Purification of human<sup>8,9</sup> or *Xenopus*<sup>10</sup> histone mRNA sequences by physicochemical methods has similarly proved

elusive. By comparison, 5-day chick embryos seem to be an excellent source of histone mRNA. When cDNA is prepared from this RNA template and sequences complementary to rRNA are removed, the resulting probe can be used to detect histone genes in the genome.

**Fig. 1** Isolation of chick histone mRNA. Five-day-old chick embryos were snap-frozen in liquid  $N_2$ , then homogenised in 7 M guanidinium-Cl in 20 mM Tris-Cl, pH 7.5, 1 mM EDTA and 1% (w/v) Sarkosyl in a Dounce homogeniser in a final volume of 30 ml. Total RNA from this homogenate was recovered as material centrifuged through 5.7 M CsCl as described elsewhere<sup>11</sup>. The clear RNA pellets were gently homogenised in 10 mM Tris-Cl, pH 7.5, 1 mM EDTA, 5% Sarkosyl and 5% phenol, then made 0.1 M in NaCl and phenol extracted with an equal volume of phenol:chloroform (1:1 v/v). RNA from the aqueous phase was collected after precipitation with ethanol, resuspended in 10 mM Tris-Cl, pH 7.4, 1 mM EDTA and 0.5% SDS, heated at 65 °C for 5 min, chilled and centrifuged on 10–40% sucrose gradients at 220,000g for 16 h at 4 °C. The 7–11S RNA was collected and refractionated on a second gradient as shown. Thirty embryos yielded 10–30  $\mu$ g of 7–11S RNA.

### Characterisation of RNA containing histone mRNA

Total RNA was prepared from 5-day-old chick embryos<sup>11</sup>, and a discrete 7–11S RNA species was resolved from other major RNAs by sucrose gradient centrifugation (Fig. 1). This RNA fraction was shown to contain histone mRNA by *in vitro* translation. When the wheat embryo cell-free system<sup>12</sup> was programmed with 7–11S RNA, the five major histones were detected as products. Before Poly(U)–Sepharose chromatography of the RNA, additional products were also detected (data not shown). However, up to 90% of the RNA isolated from the second cycle of sucrose gradient fractionation (Fig. 1) passed

through Poly(U)–Sepharose as unbound material. This RNA programmed the synthesis of histones alone as judged by analysis of protein products on two separate acrylamide-gel electrophoresis systems (Fig. 2). Although it is possible that non-histone translation products (if present) would not enter the low pH gels<sup>14</sup> (Fig. 2b), this would not be the case for SDS-urea gels run near neutral pH (ref. 13) (Fig. 2a). For both systems, the products of *in vitro* translation correspond precisely with marker <sup>14</sup>C-histones electrophoresed in the same gel. These results suggest that the poly(A) minus RNA preparation is free of detectable contaminating mRNA species.

### Characterisation of histone cDNA

Although the 7–11S RNA preparation programmed the synthesis *in vitro* of histones alone, the presence of other kinds of non-polyadenylated RNA without mRNA activity could not be excluded.

It seemed reasonable to assume that rRNA breakdown products would be the most abundant contaminants of the histone mRNAs. Rather than attempt further purification of the RNA sequences themselves, we synthesised randomly primed cDNA<sup>15</sup> and then removed cDNA complementary to rRNA from the mixture. The <sup>32</sup>P-cDNA preparation was hybridised to a vast excess of 28S and 18S rRNA and the mixture centrifuged

**Fig. 2** Analysis on polyacrylamide gels of the *in vitro* translation products of 7–11S RNA unbound to poly(U)–Sepharose. 0.5  $\mu$ g of the unbound 7–11S RNA was translated in the wheat-germ cell-free system of Roberts and Paterson<sup>12</sup> at optimal salt conditions of 80 mM  $K^+$  and 3 mM  $Mg^{2+}$ . <sup>3</sup>H-leucine-labelled translation products were electrophoresed on: a, the SDS-urea gels of Swank and Munkres<sup>13</sup>, and b, the low-pH urea gels of Panyim and Chalkley<sup>14</sup>. The gels were then sliced and the radioactivity measured. ●, <sup>3</sup>H-labelled product of *in vitro* translation; ○, <sup>14</sup>C-labelled chicken histone standards.

**Fig. 3** Preparation of  $^{32}\text{P}$ -chicken histone cDNA. DNA complementary to the 7–11S RNA sequences was synthesised with reverse transcriptase using random primers<sup>15</sup>. With 2  $\mu\text{g}$  of RNA and  $^{32}\text{P}$ -dATP of specific activity  $50 \text{ Ci mmol}^{-1}$ , we routinely obtained a yield of  $1.5 \times 10^7$  d.p.m. in cDNA. This product in  $2 \times \text{SSC}/0.5\%$  SDS was hybridised to a vast excess of 18S and 28S rRNA at  $60^\circ\text{C}$  to  $R_{0.1}$ . Ribosomal cDNA sequences were separated from putative histone cDNA sequences by sucrose gradient centrifugation (10–40% sucrose gradients centrifuged at 200,000g, 16 h at  $4^\circ\text{C}$ ). Fractions of 0.5 ml were collected from the gradient and  $^{32}\text{P}$ -radioactivity determined. The cDNA sedimenting at about 5S was pooled and used as a histone gene probe. ●,  $^{32}\text{P}$  c.p.m.; —,  $A_{254}$ .

on sucrose gradients (Fig. 3). About 30% of the cDNA sedimented with 18S and 28S rRNA, and the remaining 70% of the cDNA was present as a broad peak centred around 5S.

It was possible to test directly whether the 5S cDNA contained histone gene sequences. In a 'Southern' transfer experiment (Fig. 4), the 5S cDNA cross-hybridised to cloned sea urchin histone gene sequences (*Echinus esculentus* histone genes:  $\lambda$  clone 55, K. Murray and K. Peden, unpublished observations).

To test the proposal that this 5S cDNA contained predominantly histone coding sequences, the  $^{32}\text{P}$ -labelled cDNA was hybridised to total genome DNA from *E. esculentus*. *EcoRI*-digested sea urchin DNA was electrophoresed on agarose gels and transferred to nitrocellulose filters<sup>16</sup> (Fig. 5). It is possible to detect two closely migrating fragments (about 6 and 7 kilobases) which are identical in size to those detected by homologous *E. esculentus* histone gene probe. No other cross-hybridisation bands were detected when the chicken histone cDNA probe was used. (There are two separate size classes of histone gene repeats within the *E. esculentus* genome.  $\lambda$  Clone 55 contains the larger (7 kilobase) histone gene repeat unit (K. Murray,  $\lambda$  clone 55, K. Murray and K. Peden, unpublished observations).)

As discussed above, the most likely contaminants in the chick histone cDNA probe are ribosomal cDNA sequences. When cDNA probes from chicken rRNA were cross-hybridised to *EcoRI*-digested *E. esculentus* DNA (transferred to filters), the bands observed were readily distinguished from the characteristic 6 and 7 kilobase bands containing histone genes (Fig. 5c).

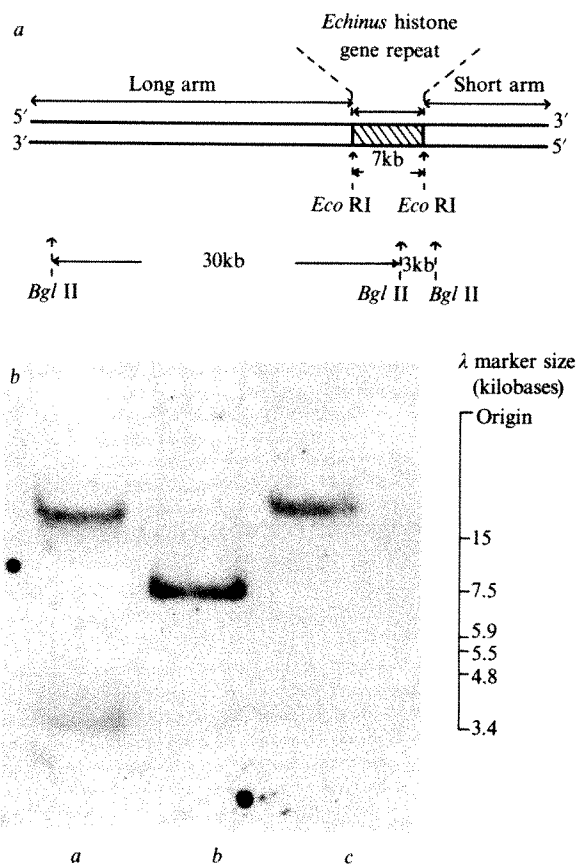

Therefore, we have shown that the 7–11S RNA prepared from chick embryos and passaged through poly(U)–Sephadex, programmes the synthesis of histones alone in an *in vitro* translation system. When cDNA is prepared from this RNA, and sequences complementary to rRNA are removed, the remaining cDNA can be used to detect sea urchin histone gene sequences. We have used this probe to detect histone genes in chicken DNA.

### The reiteration frequency of chicken histone genes

When chicken histone cDNA sequences were reannealed with genomic DNA from adult chickens, a single transition was

observed with a  $C_{0t_{1/2}}$  value of  $10^2$  (Fig. 6). This transition is distinct from that of unique sequences which have a  $C_{0t_{1/2}}$  value of  $10^3$ . These data show that histone genes are reiterated about 10-fold in the adult genome.

The rate of reannealing of histone genes is also quite distinct from that of ribosomal genes ( $C_{0t_{1/2}}$  value of 10 Fig. 6), and the data show that the chicken histone cDNA contained negligible amounts of ribosomal sequences.

**Fig. 4** Identification of chicken histone cDNA sequences, using cloned sea urchin histone genes. DNA from  $\lambda$  clone 55 (containing the 7-kilobase histone gene repeat from *E. esculentus*) was digested with *EcoRI* or *BglII*. Samples of 0.5  $\mu\text{g}$  were electrophoresed on 1% agarose gels (14 cm long, 2 mm thick, 1 cm lane width) at 60 mA for 4 h. DNA fragments were transferred to nitrocellulose<sup>16</sup>, baked in a vacuum oven for 3 h at  $80^\circ\text{C}$ , and soaked in Denhardt's solution<sup>17</sup> in  $2 \times \text{SSC}$  for 6 h at  $65^\circ\text{C}$ . Filters were dipped in  $^{32}\text{P}$ -labelled chicken histone probe (prepared as described in Fig. 3) in  $2 \times \text{SSC}/0.5\%$  SDS ( $10^6$  d.p.m. per  $\mu\text{g}$  cDNA). Strips were overlaid with paraffin oil and hybridisation allowed to proceed for 16 h at  $65^\circ\text{C}$ . After extensive washing in  $2 \times \text{SSC}/0.5\%$  SDS at  $65^\circ\text{C}$ , dry filters were put in contact with X-ray film for 2 days, and autoradiograms developed. The size of fragments were determined by reference to  $\lambda$  markers (cleaved with *HindIII* or *EcoRI*) run in the same gel, and detected by ethidium bromide staining. a, *EcoRI* and *BglII* restriction sites within  $\lambda$  clone 55. *EcoRI* excises the complete 7-kilobase histone gene insert and *BglII* cleaves the insert into two fragments. The sizes shown for the fragments are approximate. b,  $\lambda$  clone 55 restriction fragments hybridised to chicken histone cDNA and detected by autoradiography. a,  $\lambda$  clone 55 DNA restricted with *BglII*; b,  $\lambda$  clone 55 DNA restricted with *EcoRI*; c, unrestricted  $\lambda$  clone 55 DNA.

### Restriction endonuclease analysis of chicken histone genes

We have not been able to detect histone gene sequences in chicken DNA using a cloned sea urchin histone gene probe (K. Murray, K. Peden and J.R.E.W.). However, as shown in Fig. 5, the chicken cDNA probe can be used to detect *EcoRI* fragments

in sea urchin DNA of the expected size for the histone gene repeat. The reason for this apparent anomaly is probably related to gene numbers. Several hundred histone genes in sea urchin genomic DNA<sup>18</sup> could be detected by the chicken histone probe, but the 10 histone genes in the chicken genome were not detectable with the sea urchin probe. For all subsequent experiments involving restricted chicken DNA, we have used the homologous chicken probe.

Adult genomic DNA was prepared from chicken red blood cells<sup>20</sup> cleaved with the appropriate enzyme, and electrophoresed on agarose gels. After transfer of the DNA to nitrocellulose, the filters were impregnated with a solution containing <sup>32</sup>P-histone cDNA, and hybridisation was allowed to proceed at 65 °C for 16 h. Specific sequences were detected by autoradiography. Because of the sensitivity of the transfer procedure<sup>16</sup>, reiterated sequences such as ribosomal genes (100-fold reiterated in chicken, Fig. 6) are readily detected. We considered it necessary to determine the position of ribosomal gene fragments in endonuclease-restricted chicken DNA. In the event of trace contamination of histone cDNA with ribosomal cDNA sequences, ribosomal gene fragments could then be identified.

Tracks *b*, *d*, *f*, *h* in Fig. 7 show the location of ribosomal gene sequences on the same nitrocellulose filter previously used to detect histone genes. To achieve this, the hybridised <sup>32</sup>P-histone cDNA was allowed to decay sufficiently before the ribosomal cDNA probe was hybridised. Direct comparison could thus be made between the size of fragments containing the two different sets of genes within one transfer. For each of the four restriction enzyme experiments, histone genes are in different sized fragments of DNA compared with ribosomal genes.

Chicken histone cDNA was used to detect histone gene sequences in restriction endonuclease-cleaved chicken DNA. Fragments containing histone genes were detected in chicken DNA cleaved with *Bgl*II, *Eco*RI, *Bam*HI and *Hind*III (Fig. 7,

tracks *a*, *c*, *e* and *g*, respectively in Fig. 7). One outstanding feature in tracks *a*, *c* and *e* is the presence of a fragment about 15 kilobases long. We propose that this is the repeat length for the histone genes in the chicken genome.

Histone fragments generated by *Hind*III are shown in Fig. 7g. The additive size of the three *Hind*III histone DNA fragments (13–14 kilobases) is marginally less than the 15-kilobase repeat length seen consistently with *Eco*RI, *Bgl*II and *Bam*HI. One possible explanation is that a fourth histone fragment (between 1 and 2 kilobases long) is generated by *Hind*III cleavage. If the majority of this additional fragment was spacer DNA (sequences not represented in histone mRNAs), then the fragment would not be detected by the chicken histone gene probe.

Fig. 6 Estimation of histone gene reiteration frequency in the chicken genome. Reassociation reactions of <sup>3</sup>H-labelled total chicken DNA (●) and of unlabelled genomic DNA in the presence of <sup>32</sup>P-labelled histone cDNA (○) or ribosomal cDNA (■) were set up and samples taken as described by Kemp<sup>19</sup>, except that 0.18 M NaCl was used in the hybridisation buffer. The degree of reassociation was assayed using nuclease S<sub>1</sub>. At the highest C<sub>0</sub>t values, the maximum level of hybridisation was about 70%; the data have been normalised to 100%.

Fig. 5 Detection of 6- and 7-kilobase bands in sea urchin DNA, with chicken histone cDNA. Sea urchin DNA was digested to completion with *Eco*RI. Samples of 2 µg were electrophoresed on 1% agarose gels (30 cm long, 1 cm thick, 1 cm lane width) at 60 mA for 16 h. Fragments containing sea urchin histone genes were detected as described in Fig. 4. *a*, Bands (about 6 and 7 kilobases) detected with <sup>32</sup>P-*E. esculentus* histone gene probe. *b*, Bands in sea urchin DNA detected with chicken histone cDNA; *c*, Bands in sea urchin DNA detected with cDNA made on 18S and 28S chicken rRNA templates.

It is also apparent that both *Bgl*II and *Bam*HI digests reveal sequence heterogeneity in the histone genes. We have seen this heterogeneity in DNA prepared from single animals. In the case of the *Bam*HI histone gene pattern (Fig. 7e), two lower molecular weight bands are visible in addition to the 15-kilobase fragment. These two smaller bands (about 11.5 and 4.5 kilobases, respectively) together approximate to the size of the 15-kilobase repeat unit. They are not due to partial *Bam*HI cleavage, as there was no change in the histone gene pattern following further enzymatic digestion. This evidence suggests that there are two classes of histone gene repeats with respect to *Bam*HI cleavage sites; that is, one class contains one and the other class two restriction sites per histone gene repeat unit.

Two classes of histone gene sequences are also detected when chicken DNA is cleaved with *Bgl*II (Fig. 7a). One class is cleaved once per repeat to generate a 15-kilobase fragment; the other class does not contain restriction sites for *Bgl*II, as the high molecular weight DNA containing histone gene sequences hardly enters the gel. This material was not susceptible to further digestion with *Bgl*II. It is possible to separate the high molecular weight *Bgl*II histone gene fragment from the 15-kilobase *Bgl*II fragment by sucrose gradient centrifugation (data not shown). As indicated in Fig. 8 (track *c*), digestion of this high molecular weight *Bgl*II fragment with *Eco*RI gives rise to the unit histone gene repeat of 15 kilobases in the same way as does total chicken DNA when digested with *Eco*RI (Fig. 8a).

It is evident that there is some heterogeneity in the histone genes, and further, that precise details of chicken histone gene organisation require cloned fragments. However, given that restriction enzyme patterns show (1) a 15-kilobase histone unit alone, (2) a higher molecular weight histone fragment which can generate a 15-kilobase histone unit, or (3) histone gene bands

**Fig. 7** Detection of histone genes in chicken DNA cleaved with restriction enzymes. DNA isolated from chicken erythrocytes<sup>20</sup> was digested with restriction enzymes *EcoRI*, *BglII*, *BamHI* or *HindIII*. After phenol extraction and ethanol precipitation, the digested DNA (50 µg per track) was electrophoresed on 1% agarose gels, transferred to nitrocellulose<sup>16</sup> and hybridised with <sup>32</sup>P-labelled chicken histone cDNA, prepared as described in the legend to Fig. 3. After the histone fragments had been detected by autoradiography, the nitrocellulose strips were stored for 4 weeks to allow a significant level of decay of the <sup>32</sup>P-histone probe. The same nitrocellulose strips were then hybridised with <sup>32</sup>P-labelled cDNA synthesised from 18S and 28S chicken ribosomal RNA templates. The size of the fragments was determined using *HindIII*-cleaved λDNA and *Sall*-cleaved λDNA electrophoresed in the same gel as a standard. Lanes a, c, e and g were hybridised with chicken histone cDNA, and they contain chicken DNA digested with *BglII*, *EcoRI*, *BamHI* and *HindIII*, respectively. Lanes b, d, f and h were hybridised with chicken 18S and 28S ribosomal cDNAs, and they contain chicken DNA digested with *BglII*, *EcoRI*, *BamHI* and *HindIII*, respectively.

**Fig. 8** Digestion of the high molecular weight *BglII* histone gene fragment with *EcoRI*. Chicken DNA was digested to completion with *BglII* and centrifuged on 10–40% sucrose gradients in 0.01 M NaCl, 0.001 M EDTA, 0.01 M Tris-Cl, pH 7.5, at 200,000g at 4 °C for 16 h in a Beckman ultracentrifuge. The large *BglII* histone gene fragment was separated from the 15-kilobase *BglII* fragment (Fig. 7a) on fractionation of the gradient (data not shown). After *EcoRI* digestion of the DNA fraction containing the large *BglII* histone gene fragment, the DNA was electrophoresed on 1% agarose, transferred to nitrocellulose and hybridised with <sup>32</sup>P-chicken histone cDNA as described in the legend to Fig. 4. a, Histone gene sequences in total chicken DNA digested with *EcoRI*; b, large *BglII* chicken histone gene fragments fractionated by sucrose gradient centrifugation; c, Large *BglII* histone gene fragment in chicken DNA fractionated by sucrose gradient centrifugation and digested with *EcoRI*.

which add up to about 15 kilobases in size, we conclude that chicken histone genes are clustered and have a unit repeat length of 15 kilobases.

We believe this to be the first direct evidence for the histone gene repeat size in a higher eukaryote. It is not clear whether the 15-kilobase repeat contains genes coding for each of the five classes of histone proteins. The only histone gene repeats so far studied are those from sea urchin<sup>1–4</sup> and *Drosophila*<sup>5</sup>, and in these organisms at least, the histone repeat contains a complete set of histone genes.

More specifically, we have shown previously that the H5 genes (only expressed in erythroid cells) are reiterated 10-fold in the chicken genome<sup>21</sup>, and we show here that other histone genes are reiterated to the same extent. It is not clear whether H5 genes are contained within the 15-kilobase repeat. Nevertheless, there seems to be at least four to five times more DNA per repeat than is required for coding. It will be interesting to determine whether histone mRNAs are transcribed from one DNA strand (as in sea urchin<sup>3</sup>) or from both strands (as in *Drosophila*<sup>5</sup>). The report of a 15-kilobase RNA species containing histone sequences in HeLa cells<sup>22</sup> suggests the former possibility.

If 15 kilobases is representative of higher eukaryote histone gene repeat size, then this is about 2.5–3 times the length of its counterpart in sea urchin DNA and *Drosophila* DNA. If the arrangement of coding sequences and A/T-rich spacer sequences found in sea urchin histone genes<sup>4</sup> is similar in higher eukaryote histone genes, there would be a significant increase in length of 'spacer' DNA, as the length of coding regions for histones will be almost identical in all species. Nevertheless, the length of spacer DNA in a cistron cannot necessarily be equated with the evolutionary complexity of the organism. For example, the repeat length of ribosomal genes in *Dictyostelium* and mouse is comparable (38 (ref. 23) and 44 (ref. 24) kilobases, respectively) and both of these are much larger than the 11–14-kilobase repeat in *Xenopus*<sup>25</sup>. Whether the extra DNA in higher eukaryote histone genes exists as intervening sequence DNA within coding regions or as elongated spacer regions between histone coding regions, remains to be determined.

We thank Dr J. W. Beard and the office of Program Resources and Logistics, National Cancer Institute, for the purified AMV polymerase, R. Saint, K. Murray and K. Peden for their help, and K. Gross for details of clone 55 restriction sites before publication.

## Production of new cosmological perturbations during the radiation-dominated era

PURCELL (unpublished data) has noted the tendency for 'dust' particles strongly to cluster when they are coupled by viscous drag to a 'gas' whose velocity field is stochastic:

$$\frac{dV_{\text{dust}}}{dt} = \alpha \{V_{\text{gas}}(x, t) - V_{\text{dust}}\} \quad (1)$$

where  $\alpha$  ( $\text{s}^{-1}$ ) is the viscous coupling constant. The application of the Purcell clustering effect to cosmology which is considered here generates relatively large isothermal perturbations from relatively small adiabatic perturbations which will not otherwise survive damping during recombination.

The Purcell clustering effect seems at first to be paradoxical as one would expect a stochastic gas flow to randomise, rather than cluster, the positions of independent, non-interacting dust particles. The explanation is that the velocity field is not completely random but consists of disturbances that propagate at sound velocity. Therefore, on a given scale the gas velocity will be correlated for one sound travel time. In linear order in the gas velocity the dust particles always return to their original positions after the passage of an acoustic wave; in quadratic order, however, transport effects are present<sup>1,2</sup>. The accelera-

tion in quadratic order on a given scale will go as  $V_{\text{gas}}^2/l$ . In the low frequency limit, that is, for scales  $l \gg c_s \alpha^{-1}$ , particles are strongly coupled (frozen in) to the gas. The particles will therefore acquire a velocity relative to the gas of  $u \sim V_{\text{g}}^2/\alpha l$ . The mean square clustering of particles due to this anomalous motion per sound travel time is  $\delta^2 \sim (u/c_s)^2$ . The clustering of the particles at later times will not be correlated with the original clustering and will add randomly in the mean square sense. The growth of particle clustering with time will therefore be

$$\left(\frac{\delta\rho}{\rho}\right)_t^2 \sim \left(\frac{V_{\text{gas}}}{c_s}\right)^4 \left(\frac{c_s}{l\alpha}\right)^3 \alpha t \quad (2)$$

for  $l \geq c_s \alpha^{-1}$ . On small scales  $l \ll c_s \alpha^{-1}$ , the particles will always be in the process of relaxing towards the velocity  $u$  given above. The typical response to the quadratic term will be  $(1 - e^{-\alpha/\omega})u$  where  $\omega$  is the frequency corresponding to the scale  $l$ . The anomalous motion of the particles relative to the gas will therefore be  $V_{\text{g}}^2(\alpha/\omega^2)$ . In the same manner we may see that in the high frequency limit the particle clustering is given by

$$\left(\frac{\delta\rho}{\rho}\right)_t^2 \sim \left(\frac{V_{\text{gas}}}{c_s}\right)^4 \left(\frac{\alpha}{\omega}\right) \alpha t \quad (3)$$

We will give a detailed analytic derivation of the above equations elsewhere. Without considering the above physical picture the ensemble-average mean square increase of clustering can be computed using time from a formal expansion of equation (1)

**Fig. 1** Space-time diagram showing the aggregation of particles by a random acoustic field. First order motion, which integrates to zero over time, has been removed from the picture. Gaussian acoustic white noise propagates both leftwards and rightwards at velocity  $dx/dt = 1$ . The viscous coupling time of particles to the gas is  $\alpha^{-1} \approx 2$   $t$ -units, so clustering is primarily on a scale of about 2  $x$ -units. In the period shown, about 40 uncorrelated small consolidations add in the mean-square sense to give a density perturbation of order unity.

**Fig. 2** Results from many runs as in Fig. 1. The squared clustering measure  $(\delta\rho/\rho)^2$  evaluated at a spatial scale of 2  $x$ -units is shown plotted against time. Narrow lines are 10 individual runs; the heavy line is the mean of 30 further runs. For  $(\delta\rho/\rho)^2 \leq 0.3$ , squared clustering varies linearly with time, as predicted by the analytic theory. For larger  $(\delta\rho/\rho)^2$  deviations from linear growth become visible, due to numerical brownian motion on the differencing scale.

and the equation of continuity. Here we summarise the results of numerical experiments which corroborate the analytic derivations, and with an immediate application to cosmology.

An example of a numerical experiment in one dimension is shown in Fig. 1, where 128 particles are shown clumping to order unity density contrast on a scale containing about 25 particles. In this experiment density contrast was measured at the scale where  $\omega \sim \alpha$ . (Only the scale, not the number of particles shown, is relevant: 12,800 particles in the same hydrodynamic velocity field would have clustered on scales containing 2500 particles.)

Figure 2 shows  $\delta\rho/\rho$  as a function of time for 10 runs which differ only in having different random sequences of sound waves. Also shown is the mean of 30 additional runs. The secular nature of the clustering effect is evident. In equation (2), the value of the coefficient taken from the experiments agrees with the value computed analytically to within 20%. In three dimensions, equation (2) also holds, with a somewhat different numerical coefficient. The coefficient is weakly dependent on the slope of the power spectrum of the adiabatic perturbations.

We now consider the application of the Purcell clustering effect to cosmology, namely its ability to generate relatively large isothermal perturbations (which can make globular clusters and perhaps galaxies in the post-recombination era) from relatively small adiabatic perturbations which will not otherwise survive damping during recombination. Purcell clustering is able to generate these perturbations on scales much smaller than the Jeans mass, during the radiation dominated era ( $z > 10^3$ ) when, according to current views, matter and radiation are tightly coupled.

Weinberg<sup>3</sup> and others have recently pointed out that baryon non-conserving reactions at high energies (a consequence of the

charge-conjugation parity (CP) violation in super-unified theories) will 'cook' the early Universe to a unique value of entropy per baryon, one which in particular cannot vary from point to point spatially. Therefore late-time processes like Purcell clustering (or shock dissipation, see below) may well be the only way to introduce isothermal (entropy) perturbations into a cosmology.

In our cosmological application, the dust particles of Purcell clustering are individual protons and helium nuclei of the pre-recombination, radiation dominated, Friedmann cosmology; the dominant component of the gas is photons; the ionised plasma (dynamically insignificant) supplies the necessary scattering opacity to render the mean free path of photons much shorter than any other scale of interest. However, the finite mean free path of the photons will cause acoustic waves to damp long before the time when  $k = \alpha c_s^{-1}$  [ref. 4].

The baryons are viscously coupled to the photon gas primarily by radiation drag on their attendant electrons<sup>5</sup>, with

$$\alpha = \frac{4\sigma_T a T^4}{3m_p c} = 3.1 \times 10^{-11} \text{ s}^{-1} \left( \frac{z}{1300} \right)^4 \quad (4)$$

where  $\sigma_T$  is the Thompson cross section,  $m_p$  the proton mass, and  $z$  is the redshift of the epoch considered. The temperature now is taken to be 3 K. The Hubble time  $t_h$  as a function of  $z$ , when the Universe was photon-radiation dominated<sup>6</sup>, is

$$t_h = a/\dot{a} = \left( \frac{8\pi}{3} G\rho \right)^{-1/2} = 3.0 \times 10^{13} \text{ s} \left( \frac{1300}{z} \right)^2 \quad (5)$$

So,

$$\alpha t_h = 940(z/1300)^2 \quad (6)$$

The sound speed in the radiation dominated era is  $c_s = c/3^{1/2}$ , so the characteristic baryon rest mass contained in a volume of characteristic size  $c_s/\alpha$  is

$$M_P = \frac{4\pi}{3} \rho_m \left( \frac{\pi c_s}{\alpha} \right)^3 = 1.7 \times 10^{10} M_\odot \left( \frac{1300}{z} \right)^9 \left( \frac{\Omega}{0.1} \right) \left( \frac{H_0}{60} \right)^2 \quad (7)$$

If we substitute equations (7) and (6) into equation (2) we obtain

$$\left( \frac{\delta\rho}{\rho} \right)_{\text{iso}} \sim 310 \left( \frac{\delta\rho}{\rho} \right)_{\text{ad}}^2 \left[ \left( \frac{\Omega}{0.1} \right) \left( \frac{H_0}{60} \right)^2 \right]^{1/2} \quad (8)$$

where we have taken a coefficient of 10 in equation (2) from more exact calculations. Equation (8) is valid only for  $M > M_c$ , the damping scale at recombination. We note that  $M_c = 9.8 \times 10^{12} [(\Omega/0.1)(H_0/60)^2]^{1/2} M_\odot$  [ref. 7]. For  $M < M_c$  the waves driving the clustering are damped before recombination. As  $(M/M_c) = (t/t_h)^{9/4}$  gives the damping time for mass scales  $< M_c$  we get

$$\left( \frac{\delta\rho}{\rho} \right)_{\text{iso}} \sim 2 \left( \frac{\delta\rho}{\rho} \right)_{\text{ad}}^2 \left( \frac{M}{M_P} \right)^{5/18} \left[ \left( \frac{\Omega}{0.1} \right) \left( \frac{H_0}{60} \right)^2 \right]^{7/6} \quad (9)$$

Equations (8) and (9) say, roughly, that 10% adiabatic perturbations will generate 1% isothermal perturbations anywhere in the mass range  $10^9$ – $10^{12} M_\odot$ .

In the 'pancake' theory of galaxy formation as originally proposed by Zel'dovich, Sunyaev *et al.*<sup>8–11</sup>, the density contrast before recombination is the same at all scales with a value between  $10^{-3}$  and  $10^{-4}$ . In this case Purcell clustering is insignificant. However, calculations by Silk<sup>12</sup> and by Peebles and Uy<sup>13</sup> seem to show that a considerably larger density contrast on the scale of the pancakes is necessary to produce galaxies, say  $10^{-2}$ . As limits of  $< 10^{-3}$  on the large-scale inhomogeneity can be set from the microwave background<sup>14</sup>, it seems likely that a viable perturbation spectrum must have  $\delta\rho/\rho$  increasing towards smaller masses and reaching the 10% level well within the mass range where Purcell clustering becomes important. In that case the condensation of sub-galactic units renders the subsequent collapse of the pancake stellar dynamical rather than hydrodynamical. The formation of dense, cold sheets needed for fragmentation into galaxies is impossible, and the whole pancake hypothesis must be reexamined.

The Purcell clustering process is physically distinct from another process which can generate entropy fluctuations, namely the dissipation of shock waves that are formed by wave steepening, and wave-wave interactions. For 10% adiabatic fluctuations described above, the Purcell clustering seems to dominate for two reasons: first incoherent acoustical disturbances steepen much more slowly than plane waves<sup>15</sup>, and second shock dissipation goes as the cube of shock strength, so weak (10%) shocks are not very dissipative.

## Evidence for X-ray emission from Kepler's supernova remnant

THE remnant of Kepler's supernova of 1604 AD has long eluded detection at X-ray wavelengths, principally because of its proximity to a source confused region in the direction of the galactic centre. We present here the first evidence for weak soft X-ray emission from Kepler's remnant, which was beyond the capability of earlier X-ray surveys<sup>1</sup> but is now possible because of the increased sensitivity provided by the low energy detectors (LEDs) of the A 2 experiment on the HEAO 1 spacecraft. (The A 2 experiment on HEAO 1 is a collaborative effort led by E. Boldt of GSFC and G. Garmire of CIT, with collaborators at GSFC, CIT, JPL, and UCB). The LEDs are described in detail by Rothschild *et al.*<sup>2</sup> Briefly, the data reported here were acquired using the LED1 narrow field of view (1.5° FWHM in the scan direction) which has an effective area of 175 cm<sup>2</sup> and is sensitive to X-rays between 0.2 and 3 keV.

The region of sky containing Kepler's remnant was scanned by LED1 between 11 and 16 March 1978, and Fig. 1 shows the results of superposing five scans during this time interval. The count-rate data are complex owing to the concentration of X-ray sources in the direction of the galactic centre. However, a new soft source, denoted H1735-21, is evident in the data as a count-rate peak centred at a scan angle of 178.2°. This is just resolved from the GX9+9 region. The solid line in Fig. 1 indicates a least-squares fit of the LED1 angular response function to the data bounded by the sources GX9+9 and GX3+1. The 90% confidence error box derived from this fit is depicted in Fig. 2, together with the positions of all known nearby X-ray sources. Incorrect modelling of the background could introduce small systematic error (~0.1°) in position of narrow direction of the error box. Kepler's remnant lies within our error box, and is therefore proposed as the probable identification. We have checked other classes of object which could produce soft X-ray emission, but no other compelling counterparts were found within the error box. The Uhuru source 4U1730-22 (ref. 3), which lies at the edge of the 90% confidence error box, is an unlikely identification because it is

**Fig. 1** A superposition of five scans of HEAO A-2 LED data (0.3-3.0 keV). A typical error bar around the region of interest is shown. The solid curve represents the best fit to the triangular response of our detectors to H1735-21 plus the local background. GX9+9 (angle = ~174) and GX3+1 (angle = ~183) constrained the use of background data.

known to be a transient<sup>4</sup>. The spectrum of transients are hard near maximum intensity. The absence of H1735-21 in medium and high energy detectors (S. Pravdo, personal communication) precludes it being the transient detected during an 'on-state'. Our data are consistent with the source being constant during the period of observation. However, because the source is just at our level of detectability, we are insensitive to decreases in intensity.

The distance to Kepler's remnant remains uncertain. Because it lies in the direction of the galactic centre the application of normal distance measuring techniques (for example, neutral hydrogen absorption observations) is impossible. A position within the nuclear bulge, with distance of about 10 kpc, has been invoked to help explain the comparatively large angular displacement from the galactic plane. The historically inferred apparent magnitude of -3, and its classification as Type I (ref. 5), suggest a distance of between 3.5 and 6 kpc, assuming an

**Fig. 2** A map of the region shows the derived HEAO A-2 90% confidence error box. The position of Kepler's SNR as well as all known nearby X-ray sources is shown. Note the position of 4U1730-22 is at the edge of the box.

absolute magnitude for a Type I supernova of  $-19$  and visual absorption in the range  $0.5$  to  $1$  mag  $\text{kpc}^{-1}$ . Recent unpublished observations of the reddening of the optical remnant of Kepler's supernova (I. J. Danziger, personal communication) suggest a distance of  $\sim 4$  kpc.

The intensity derived for H1735-21 is  $(6.3 \pm 1.5) \times 10^{-2}$  counts  $\text{cm}^{-2} \text{s}^{-1}$  between  $0.3$  and  $3.0$  keV, corresponding to a flux of  $(2.4 \pm 0.6) \times 10^{-10}$  erg  $\text{cm}^{-2} \text{s}^{-1}$ , assuming a power law spectrum with a photon index of  $-2.0$  and a column density of  $10^{22}$  H-atoms  $\text{cm}^{-2}$ . (The count flux as well as the energy flux could be uncertain by a factor of 2 due to uncertainties in background subtraction and incident spectrum.) The assumed hydrogen column density, probably appropriate for Kepler's remnant regardless of distance uncertainty, gives an intrinsic X-ray luminosity in the energy range  $0.3$ – $3$  keV of  $\sim 180 \times 10^{35}$  erg  $\text{s}^{-1}$  for a distance of  $10$  kpc, reducing to  $\sim 28 \times 10^{35}$  erg  $\text{s}^{-1}$  for a distance of  $4$  kpc. The former value is greater than for any other known young supernova remnant, including the Crab Nebula, and must cast further doubt on Kepler's remnant lying at the galactic centre distance. The latter value is more acceptable, being comparable with that of other young supernova remnants such as that for Tycho's SNR and Cas A.

On the near side of the Galaxy, six supernovae recorded in historical times have been identified with remnants<sup>5</sup>—those of 185 AD (remnant RCW 86), 1006 AD (PKS 1459-41), 1054 AD (the Crab Nebula), 1181 AD (3C 58), 1572 AD (Tycho) and 1604 AD (Kepler). The objects Cas A, RCW 103 (ref. 6), and MSH 11-54 (refs 7, 8) are also believed to be the remnants of supernovae which have occurred within the past two millennia but were not recorded historically. All the above mentioned objects have previously been detected in X-rays with the exception of Kepler's remnant. For this reason, it has long been classified as a highly likely X-ray source<sup>9,10</sup>, although problems of confusion and sensitivity have thwarted previous attempts at detection. HEAO 2 will now allow the detection reported here to be confirmed, the source to be imaged, and its spectrum to be more accurately determined.

We thank G. Riegler, P. Agrawal, E. Boldt and the GSFC group for their contributions towards the development of the LED detectors. This work was supported by NASA contract NAS 5-23315.

## A peculiar galaxy system in Hydra

IN the course of scanning the Palomar Sky Survey, I noticed what appeared to be a large and a small elliptical galaxy interconnected by a long straight bridge which could have been a radial jet from the larger galaxy. Furthermore a comparison between red and blue prints showed the smaller galaxy to be

**Fig. 1** The cluster of galaxies containing the peculiar system (from the blue print of the Palomar Sky Survey). Identifications of galaxies are as follows: the peculiar system (galaxy 1 = MCG -1-22-6 = F-272; galaxy 2 = F-271; galaxy 3 = MCG -1-22-7 = F-273). Galaxy 4 = NGC2583 = MCG -1-22-8; galaxy 5 = MCG -1-22-9; galaxy 6 = MCG -1-22-10. The optical identification of the radio source PKS0820-047 is also indicated. (Reproduced with permission from the National Geographic Palomar Observatory Sky Survey.)

extremely blue, and thus highly unusual. Detailed enlargement of the images suggest that the larger galaxy may possess chaotic filaments akin to those in M82 or NGC1275. The spectroscopic observations described here show that, as expected, the two galaxies have strong narrow emission lines, but also that a third neighbouring galaxy is involved.

The system concerned appears as part of a medium-poor cluster of galaxies at  $1950: 8^{\text{h}} 20.7^{\text{m}}, -4^{\circ} 50'$  in the constellation of Hydra (see Fig. 1). The two larger members of the peculiar system are recorded in Vorontsov-Velyaminov's *Morphological Catalogue of Galaxies*<sup>1</sup> (MCG) although the system is apparently not included in his *Atlas of Interacting Galaxies*<sup>2</sup>. (The designations F-271, F-272 and F-273 refer to the selection of these objects for my current survey of 'compact and bright-nucleus galaxies'<sup>3</sup>.)

Figure 2 shows further enlargements of the peculiar system. These plates are made from a different copy of the Palomar Sky Survey from that on which the pair of ellipticals were originally noticed and the straight bridge between those galaxies (galaxies 1 and 2) is, in this case, not as conspicuous as it appeared on the red print of the first copy. This seems to be why Vorontsov-Velyaminov<sup>2</sup> did not pick it up; had he done so it would have made an extreme example of his 'bottle form' category.

The extreme blue colour of galaxy 2 is readily apparent by comparing its images in Fig. 2a and b; similarly, the red filaments of galaxy 1 (the appearance of the outer parts of the galaxy is slightly affected by the mottled sky background of the paper print). Galaxy 3 seems to possess bluish outer regions and condensations.

Spectroscopy was carried out in 1978 November/December with the image tube spectrograph on the 1.9 m Radcliffe Reflector at the South African Astronomical Observatory. Unwidened spectra at  $210 \text{ \AA mm}^{-1}$  covering  $3,700$ – $7,000 \text{ \AA}$  with a strong peak in the blue were obtained (and reduced in the same manner as described elsewhere<sup>3</sup>). The spectrum of galaxy 1 shows strong [O III]5007+4959 as well as narrow H $\beta$ ; the emission region seems more extensive than the central core of the galaxy (it could be filaments). The uncorrected redshift is found to be  $z = 0.0218$  (probable error 0.0005). The spectrum of galaxy 2 reveals strong narrow lines of [O II]3727, H $\beta$ , [O III]5007+4959 and H $\alpha$ , with  $z = 0.0230$ . Unexpectedly, galaxy 3 also turned out to have emission lines though they are weaker; it has narrow [O II]3727, H $\beta$  and [O III]5007+4959 with  $z = 0.0226$ . NGC2583 (galaxy 4) seems to have a con-

ventional absorption spectrum with  $z=0.0197$  (based on the G-band and H and K lines, with a slight uncertainty in identification). Galaxies 5 and 6 proved to be of low surface brightness and identification of features in their spectra proved very difficult; both may have very weak H $\beta$  emission (as might be expected for such late type spirals) with  $z=0.0240$ . (As all six galaxies are relatively faint, the spectrograms show appreciable sky contamination. Thus the overall quality does not permit quantitative measurements of line strengths and so on).

The strong narrow emission lines of galaxies 1, 2 and 3 indicate abnormal nebular emission—as is not uncommon in interacting systems (such as, nos 44–45–46, 156–157, 199, 204 and 210 in my current survey<sup>3</sup>). The astrophysical interpretation of such is usually controversial. In this case it looks as though galaxy 2 has either been ejected from galaxy 1, or at least has passed through it. If the latter is the case, the tidal turmoil has evoked a sudden wave of star formation providing the excitation mechanism for the nebular emission. But are the red filaments of galaxy 1 merely tidal in origin, and how does galaxy 3 fit into such a picture? The alternative would be in line with ideas favoured by Arp<sup>4</sup>—that galaxy 1 is some sort of active galaxy and galaxy 2 has somehow been thrown out from it—red

filaments would support ejective or explosive processes. The notion of an exploding galaxy immediately brings to mind M82 and one may question whether this is really an explosion or are the active trio merely a manifestation of galaxies drifting through dust<sup>5</sup>? None of these explanations seem satisfactory and further speculation should probably await the photography and spectroscopy of this system by larger telescopes.

Figure 2 also indicates some particularly red and blue stars; it is a little unusual that they should appear to lie so close to the galaxies but there is nothing to suggest that they are not foreground stars. Likewise the radio source PKS0820-047<sup>6</sup> (= OJ-033=4C-4.26) identified with an 18th magnitude starlike object lies close enough to appear in Fig. 1.

I am grateful for the hospitality at the A. J. Dyer Observatory of Vanderbilt University, Nashville, Tennessee (where this object was originally noticed in early 1977) and to the director of the South African Astronomical Observatory for observing time.

## A measurement of the Rydberg constant

THE Rydberg constant is of key importance in spectroscopy and, because it may be expressed as the product of several fundamental physical constants, it also plays an important part as an auxiliary constant in the evaluation of the fundamental constants of physics<sup>1</sup>. We report here a value of the Rydberg constant that is derived from the measurement of three of the fine-structure components of the hydrogen Balmer- $\alpha$  line by the saturable absorption technique<sup>2</sup>. The earlier measurements of the Rydberg constant by conventional spectroscopy and by the laser saturation absorption spectroscopy technique have been reviewed by Series<sup>3,4</sup>.

A c.w. tunable dye-laser (CR-599), pumped by the 514 nm line of an argon-ion laser (SP-170), was used as the source of monochromatic radiation. The dye-laser beam was split into counter-propagating saturating ( $\sim 10 \text{ mW}$ ) and probe beams ( $\sim 4\%$  of the saturating power), about 2 mm in diameter, these crossed at a small angle, about 1 mrad, at the centre of a Wood's discharge tube which contained hydrogen gas and residual water vapour. The central portion of the tube was 20 mm in diameter and 250 mm long. The voltage gradient, for a discharge current of 30 mA, at a hydrogen pressure of about 6 Pa (0.05 torr) was  $0.5 \text{ V mm}^{-1}$ . The dye-laser was adjusted to operate at the Balmer- $\alpha$  wavelength by making rapid measurements with a digital wavemeter<sup>5</sup>. The wavelength of the radiation was measured with a plane Fabry-Perot interferometer<sup>6</sup>, whose plates were silvered to give a finesse of about 35. The length of the etalon was about 97.2 mm and was stabilised to be an integral number of half-wavelengths of the radiation from a helium-neon laser which was locked to one of the fine-structure components of  $^{127}\text{I}$ . The wavelengths of these components are accurately known in terms of the  $^{86}\text{Kr}$  definition of the metre.

**Table 1** Values obtained for the reciprocal wavelengths of the fine-structure components and the random, systematic and total uncertainties in the last digit quoted

Fine-structure component	Wavenumber (m <sup>-1</sup> )	Uncertainties (s.d.)			No. of observations
		Random	Systematic	Total	
2P <sub>3/2</sub> -3D <sub>5/2</sub>	1,523,307.0507	30	104	108	39
2S <sub>1/2</sub> -3P <sub>3/2</sub>	1,523,336.5129	61*	135	148	13
2P <sub>1/2</sub> -3D <sub>3/2</sub>	1,523,340.0281	65*	130	145	13

\* These random errors are correlated

Signals from a confocal Fabry-Perot interferometer (125 MHz fsr) and the plane Fabry-Perot interferometer, together with the saturated absorption signal, were digitised and recorded. A computer was used to fit fringe intensity curves to the etalon signals, and also to fit combined lorentzian and gaussian distributions to the saturated absorption signal. Corrections were made to the measured wavelengths in order to allow for the phase-shift at the etalon mirrors<sup>6</sup> (-2.6 p.p.b., that is -2.6 parts in 10<sup>9</sup>), Stark shifts<sup>7</sup> (4.6 p.p.b., -3.3 p.p.b., and 1.3 p.p.b.), a correction for a possible pressure shift (4.4 p.p.b.) and for the unresolved cross-over signals<sup>8</sup> (-4.2 p.p.b., -8.4 p.p.b. and -13.8 p.p.b.), where the corrections for the three components have (where different) been given in the same order as in Table 1. The results were investigated for possible systematic dependence on the discharge conditions and laser power and, although no significant effects were found, an allowance was made for possible dependence on these parameters in making the systematic error assignments. The width and the asymmetry (which averaged to zero) of the resonances were also studied<sup>9</sup>.

**Table 2** Values obtained for the Rydberg constant since 1969

	Rydberg constant less 10,973,730 m <sup>-1</sup>	Standard deviation uncertainty (10 <sup>-3</sup> m <sup>-1</sup> )
Taylor <i>et al.</i> (1969) (review value)	1.20	1,100
Masui (1971)	1.88	800
Kessler (1973)	2.08	850
Kibble <i>et al.</i> (1973)	2.60	800
Hansch <i>et al.</i> (1974)	1.43	100
Goldsmith <i>et al.</i> (1978)	1.476	32
Present work	1.513	85

The values obtained for the wavenumbers of the three fine-structure components studied are given in Table 1, together with the random and systematic uncertainties (expressed as standard deviations) of the last digit quoted. These three values were ratioed with those calculated by Erickson (ref. 10 and personal communication) and then combined with his assumed Rydberg value to give a weighted mean value of 10,973,731.513(85) m<sup>-1</sup> for the Rydberg constant; our three Rydberg values agreed to 0.003 p.p.m. The standard deviation uncertainty assigned to our Rydberg measurement consists of the random uncertainty of the mean of 0.0021 m<sup>-1</sup> (55 independent results) which has been combined with the root sum square of the systematic uncertainties, expressed as a standard deviation, of 0.0082 m<sup>-1</sup>. Our result is in excellent agreement with other measurements of the Rydberg constant that have been made during the past 10 years<sup>8,11-15</sup>, (see Table 2 and ref. 4), particularly the saturable absorption measurement of Hansch *et al.*<sup>8</sup> and the laser polarisation spectroscopy measurement of Goldsmith *et al.*<sup>15</sup>.

We thank R. E. Shawyer for assistance with the computer analysis of the data, and W. R. C. Rowley and A. J. Wallard for

helpful discussions and the loan of an iodine stabilised helium-neon laser.

## Optical anisotropy of carbon fibres

TECHNIQUES based on the interference of polarised light have been used to investigate double refraction in transparent materials due to the structural anisotropy of crystalline solids and strain birefringence in amorphous solids<sup>1</sup>. Forrest and Marsh have discussed<sup>2,3</sup> reflection methods and have used them to examine the anisotropy of the opaque solids carbons and cokes. As graphite is a uniaxial crystal with an optical c-axis perpendicular to the layer planes, polarised light incident on the layer-planes is not affected so that a polished section with this orientation appears isotropic. However, polarised light reflected by the prismatic faces is rotated and a polished section in this orientation shows optical anisotropy. By inserting a one wavelength retarder plate at 45° in front of the analyser of a polarising reflection-microscope with crossed polariser and analyser, interference colours are produced from which the orientation of the surface crystallites can be determined.

Polished cross-sections of carbon fibres made from mesophase pitch and examined in polarised light have a narrow 'Maltese-Cross' pattern with interference colours, deep yellow and blue, in alternate quadrants. By using pyrolytic graphite as a reference material, it can be inferred from the colours that the layer planes are arranged radially in the cross-section. Thin cross-sections which were cut and examined in a transmission electron microscope have confirmed this structure.

High modulus carbon fibres made by the RAE process<sup>4</sup> from textile PAN fibres (a polyacrylonitrile copolymer) also show a 'Maltese-Cross' but the pattern and the interference colours depend on the diameter of the PAN precursor fibre and the conditions used to convert it to a carbon fibre. The PAN fibres are first oxidised<sup>4</sup> under tension at temperatures in the range 200-300 °C. At the lower temperature, about 200 °C, the rate of chemical reaction is slow and the rate of diffusion is sufficiently fast to prevent a significant oxygen gradient. At higher temperatures, ≥220 °C, the reaction rate increases so that the oxidation becomes diffusion controlled and if oxidation is incomplete there is<sup>5,6</sup> a core with little oxidation surrounded by a more oxidised sheath. Longitudinal section (Fig. 1a) of a carbon fibre made after incomplete oxidation shows two zones and cross-sections (Fig. 1b) show two concentric interference figures separated by a dark (isotropic) ring, and having a centre which is also isotropic. From the interference colours these patterns have usually been interpreted<sup>7</sup> as an inner zone of radially orientated

a

b

**Fig. 1** Polished sections of carbon fibres made from 3 denier polyacrylonitrile copolymer fibre by heating in air for 6 h at 220 °C, then carbonising and heating to 2,500 °C. Polariser and analyser crossed. *a*, Longitudinal section; *b*, cross-section.

layer-planes surrounded by an outer zone of layer-planes with circumferential orientation. Extensive oxidative etching in a plasma is said<sup>8</sup> to support this interpretation.

But no mechanism for the formation of the radial-circumferential structure has been proposed; and investigations using electron microscopy have provided positive evidence that layer-plane orientations in cross-sections of carbon fibres are random. Thus longitudinal sections cut from carbon fibres, made as described above and which in the optical microscope appeared to have a sheath and core, have always appeared uniform in the electron microscope; although selected area diffraction and (002) dark field images (Fig. 2*a*) showed that layer planes of the crystallites were parallel to the fibre axis, there was no preferred distribution between the two zones<sup>9</sup>. Moreover, tilting the specimen produced no overall change; radial-circumferential structures would have had pronounced effects. Transverse sections, ~50 nm thick, have recently confirmed that there was no preferred orientation of the layer planes in the fibre cross-section. Figure 2*b* shows that there were no obvious differences between the phase-contrast lattice-fringe images obtained from the core and sheath regions, and the continuous rings of the selected area diffraction pattern show that the orientations were random.

This raises the possibility that the optical anisotropy seen in the carbon fibres was caused not by structural anisotropy but by strain birefringence, and several recent observations support this.

First, optical activity and interference colours have been seen in reflected polarised light from the glassy carbon matrix in which carbon fibres had been embedded (see Fig. 3*a*); the glassy carbon was made from furfuryl alcohol resin carbonised to 1,000 °C only, a temperature at which stress graphitisation could not have occurred<sup>10</sup>. (Similar optical activity has been observed at the stressed interfaces formed when pieces of furfuryl alcohol resin-carbonised to 450 °C were coated with further resin and then carbonised at 1,000 °C.)

Second, cutting thin cross-sections of the carbon fibres caused knife damage; the shattered appearance (Fig. 3*b*) suggests differential residual stresses in the outer and inner zones.

Third, etching with argon ions for short erosion times, <60 min, caused similar amounts of erosion in the sheath and core and no features were seen to indicate any differences in structure even at magnifications of  $\times 20,000$ . Figure 4*a, b* shows both transverse and longitudinal sections, in which the lower erosion rate of the material between the sheath and core may have been due to its being unstressed.

It is, therefore, suggested that the patterns in both the glassy carbon matrix and in the carbon fibres themselves are caused by strain birefringence. Furfuryl alcohol resin is thermosetting and shrinks by about 20% when heated to 1,000 °C; it forms a rigid cross-linked structure with no plastic flow<sup>11</sup> when it is carbonised. This shrinkage will cause a circumferential tensile stress in the matrix around a fibre. Also, it is thought that a radial oxygen gradient in incompletely oxidised PAN fibres may induce internal strains in the resulting carbon fibres. The carbon yield<sup>12</sup> from

a

oxidised PAN fibres is about 50%, and that from unoxidised fibres about 30%; thus any differences in oxygen content will lead to density differences and probably also to differences in the transverse Young's modulus (the dependence of longitudinal Young's modulus on oxygen content is well established)<sup>4</sup>. When a partially oxidised PAN fibre is carbonised there will be a greater carbon yield in the oxygen-rich sheath than in the core. As the fibres do not melt or flow, as they are carbonised, the core will be restrained from shrinking by the more densely packed sheath so that a radial tensile stress will develop in the core with a corresponding circumferential compressive stress in the sheath. The region between the sheath and core is not stressed and seems optically isotropic.

The strain field of a carbon fibre embedded in a glassy carbon matrix (as in Fig. 3*a*) has cylindrical symmetry; hydrostatic stresses around and within each fibre lead to the shear strains shown in Fig. 4*c*.

It is suggested that the presence of a 'Maltese-Cross' pattern in the core of a fibre will depend on a non-uniformity of Young's modulus of the core carbon. If the Young's modulus were constant, the hydrostatic tensile stresses would deform the core evenly; each square of a grid in the core of Fig. 4*c* would be enlarged without distortion and the core would appear optically isotropic in the polarising microscope. But, if there had been an oxygen gradient then the transverse Young's modulus of the core carbon would decrease towards the centre of the fibre, the deformation of the core would be non-uniform and the maximum elongation would be circumferential giving the observed optical anisotropy, the pattern of the core having the same interference colours as that of the glassy carbon matrix; the distortion towards the centre of each fibre is too small to have an effect and it appears optically isotropic. This model also explains why the 'Maltese-Cross' pattern is less evident in micrographs of

carbon fibres made from well-oxidised PAN fibres as it is not seen when the oxidation kinetics do not lead to a significant oxygen gradient.

Transmission electron microscopy of thin transverse sections of carbon fibres made from PAN has shown that the structure is random; it is suggested that the observed optical anisotropy is due to stress in the fibres caused by differential shrinkage between the sheath and core. The optical anisotropy of carbon fibres made from different PAN precursor fibres often differs from a 'Maltese-Cross' and thin-sections of these are being examined.

**Fig. 4** Polished sections of carbon fibres in glassy carbon argon ion etched; *a*, cross-section fibre diameter 11.8 µm, etched 30 min; *b*, longitudinal section fibre diameter 10 µm, etched 60 min; *c*, a quadrant of the distortion in and around a carbon fibre embedded in a glassy carbon matrix.

I thank Dr S. C. Bennett and Dr D. J. Johnson for the electron-microscopy of thin sections of carbon fibres from pitch and PAN.

## Evidence for a widespread late Pleistocene humid period in the Kalahari

THE nature and extent of late Quaternary environmental changes in the interior of southern Africa are obscure, in part because of a lack of absolutely dated sediments, and landforms of clear palaeoenvironmental significance. Here I present evidence to show that, during the period 17,000–15,000 BP, the Kalahari, now a semi-arid area with little or no surface drainage, was a region of widely distributed small lakes, as a result of a substantial increase in rainfall.

A belt of pans (small dry or ephemeral lakes) with areas between 0.3 and 7 km<sup>2</sup> extends along the main Kalahari watershed, between latitudes 23–26°S (Fig. 1). The pans are situated

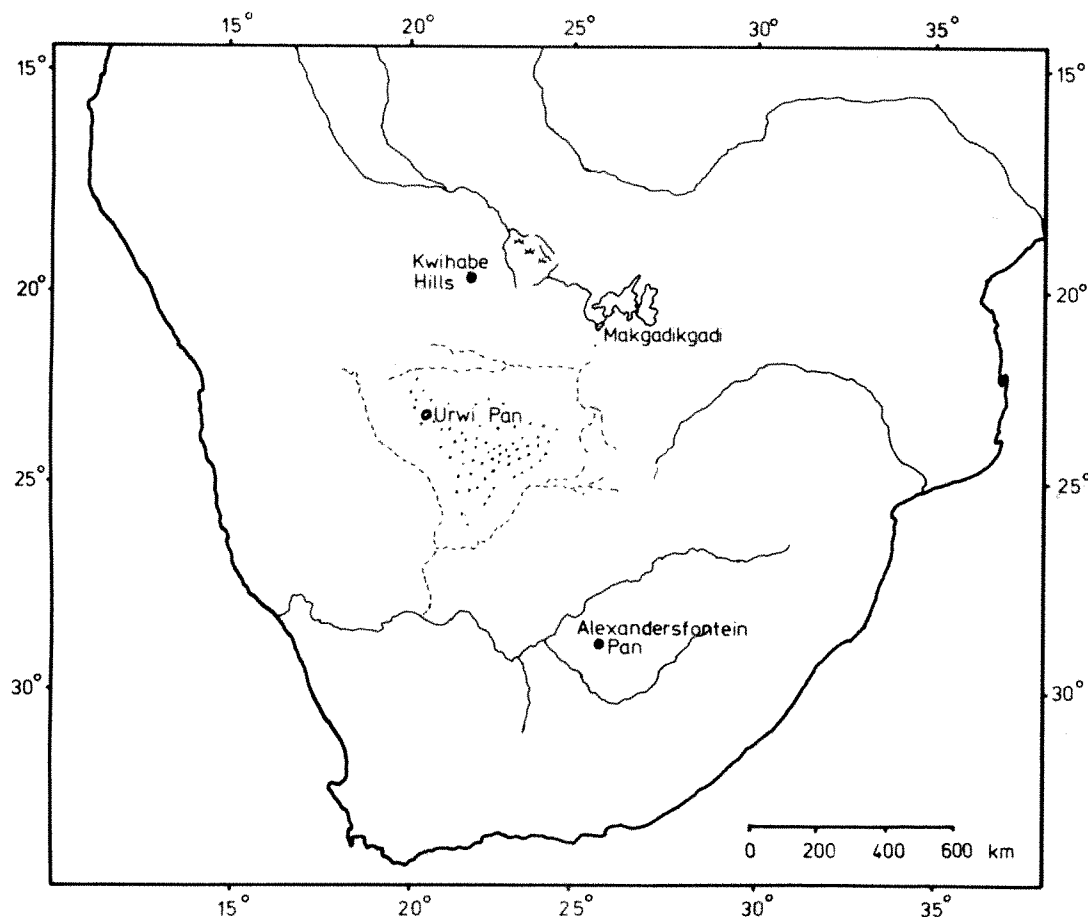

**Table 1** <sup>14</sup>C dates for Urwi pan stromatolites

Pta 2212	15,790 ± 110 BP
Pta 2213	15,610 ± 125 BP
Pta 2146	16,000 ± 160 BP
Pta 2150	16,255 ± 700 BP

in small, shallow, isolated enclosed depressions floored by calcareous and saline clays and sandy clays, laid down in shallow lacustrine conditions. Crescentic dunes on the southern margins of the pans indicate a deflation origin for the depressions<sup>1</sup>. The pans thus represent a microcosm of late Quaternary environmental change in the region, with deflation in arid or sub-arid conditions alternating with humid lacustrine conditions.

<sup>14</sup>C dates (Table 1) obtained from stromatolites recovered from a site 1–1.5 m above the present level of Urwi pan (Fig. 2) indicate that shallow lacustrine conditions prevailed in the pans 17,000–15,000 yr ago. The stromatolites are of spheroidal morphology, indicating their formation in permanent, wave agitated waters<sup>2</sup>. Changes in their internal structure suggest increased wave action during the period of their formation. The stratigraphic position of the stromatolites (Fig. 2) indicates that they pre-date the last phase of aeolian activity at the pans, and probably represent the final stages of full lacustrine conditions. Complementary sedimentary evidence<sup>1</sup> suggests that permanent alkaline lakes 2–3 times the present area of the pans were succeeded by increasingly arid conditions, in which saline clays were deposited in rapidly contracting seasonal or ephemeral lakes, on the margins of which a sandy wash was laid down. Subsequent deflation of the sandy deposits resulted in the formation of the inner dunes.

Today, mean annual rainfall in the area totals 300–400 mm, with pan evaporation exceeding 3,000 mm. It is thus not surprising that water bodies are ephemeral and runoff from the permeable surface sands negligible (<2 mm per yr). The existence of permanent lakes covering areas 2–3 times the area of

**Fig. 1** Southern Africa, showing location of pans, and sites mentioned in text.

Fig. 2 Stratigraphic section at Urwi pan with location of stromatolites. All pans in region have an essentially similar stratigraphy.

the present pans is clear evidence that the Kalahari experienced substantially increased late Glacial rainfall, reduced evaporation, or a combination of both. Other workers in southern Africa<sup>3</sup> have assumed a 5–6 °C lowering of temperature at this time. By analogy with other stations in the interior of southern Africa with a mean annual temperature of 15–16 °C, compared to the 20–21 °C experienced in the southern Kalahari today, evaporation rates 17,000–15,000 yr ago would have been 40–50% lower. Similar comparisons, using data in Midgeley and Pitman<sup>4</sup> suggest that decreases in temperature and evaporation of this order would have led to increases in surface runoff to 10–20 mm per yr. Even allowing for this, rainfall increases of 1.5–2 times present amounts would have been necessary to sustain permanent lakes in the region, as the catchment areas for the lakes are extremely small (at most 10–15 km<sup>2</sup>). The potential contribution from shallow groundwater seepage is difficult to assess, but Verhagen *et al.*<sup>5</sup> demonstrate that significant recharge to shallow groundwater is taking place today in the northern Kalahari, where rainfall totals are 450–600 mm per yr. The increases in rainfall suggested must therefore be regarded as a maximum.

The evidence from the pans thus considerably extends the area of southern Africa known to have experienced increased late Glacial rainfall, and strongly suggests that the climate of the whole of the interior of the subcontinent was sub-humid at this time. Then the arid zone in southern Africa must have largely disappeared, except for isolated refuges along the Namib coast.

Butzer *et al.*<sup>3</sup> have calculated that rainfall totals were 123% of present amounts 16,000 yr ago in Alexandersfontein pan area near Kimberly (28°50' S); Cooke<sup>6</sup> estimated a threefold increase in rainfall for the Kwihe Hills area in northwestern Botswana (20° S), based on cave deposits with <sup>14</sup>C ages ranging from 14,000 to 17,000 BP. High lake levels in the Makgadikgadi depression some 20,000 years BP<sup>7</sup> may indicate that the period of increased rainfall started some 5,000 yr before this.

The picture of late Glacial climatic conditions in southern Africa which is now emerging is significantly different to that of the rest of the continent, which seems to have been dry at this time, with the southern margins of the Sahara up to 500 km south of their present position and low lake levels in east Africa; only parts of north Africa experienced wetter climates during this period.

The increased rainfall in the Kalahari at this time was probably the result, not of increased penetration of the subcontinent by winter cyclonic rains as Butzer *et al.*<sup>3</sup> suggest, but of greater summer rainfall due to a more southerly position of the Inter Tropical Convergence Zone. This was in turn the result of strengthened Northern Hemisphere circulations. Modern

parallels support this argument, with heavy rainfall in the region in recent years (1972, 1974–5, 1977–8) being associated with the persistence of the Inter Tropical Convergence Zone near its southerly limits (19–20° S). Desiccation of the interior of southern Africa was not well advanced until 9,000 BP, and was associated with much higher temperatures<sup>8</sup>, at a time when rainfall over much of Africa between the Equator and the northern Tropic was substantially greater than at present<sup>9</sup>. Equally interesting is the lack of correlation with Australia, where the late Glacial was cold, dry and windy<sup>9</sup>.

I thank Dr J. C. Vogel for <sup>14</sup>C determinations on the stromatolites.

## Tracing the wake of a flying bird

STUDY of the classical problem concerning “the way of an eagle in the air”, when applied to flapping bird flight, offers many difficulties. All dynamic interactions between an object and a fluid medium in which it moves are ciphered in the structure of its wake, but the wake behind a flying bird is difficult to work with because it is an invisible and very short-lived formation; moreover, its structure must be complicated as the bird's wings are working in a constantly changing manner. I report here the results of wake visualisation experiments carried out during short flights of a chaffinch (*Fringilla coelebs*) and a brambling (*F. montifringilla*) in enclosures. The general configuration of a wake is given, but no measurements have been made: in general, to extract some quantitative information from the wake structure, a more precisely documented picture of the dynamics of its formation is needed.

**Fig. 1** Multiflash photographs and a scheme depicting cross-sections of the wake of a flying bird. *a*, Side view of the wake. A winding jet is visible with two almost vertical hollow vortex rings as if 'threaded' on it; the cross-sections of the rings' top and bottom parts are represented by the circular outlines—a pair for each ring. *b*, Side view with three vortex rings visible. A light vertical stripe is produced by illumination of the wake in the transversal plane. *c*, Front view of the wake. *d*, The same wake as in (*c*) photographed synchronously from the side. The axis of the thick apple-shaped vortex ring, the only one visible, is orientated rather vertically. This and the scarcity of the dust particles in the fore-part of the 'apple' allows us to see its frontal cross-section in the form of a circular outline near the bird's right wing (*c*). The left-side half of the vortex ring is not visible, as there were no dust particles around the bird's left wing (the same is also true for all other photographs). The linear scale on *c* and *d* is relevant more for the wake than for the bird image. *e*, The scheme elucidating the spatial relationships of vortex ring cross-sections on synchronous photographs (*c, d*); as in the photographs only the right-side half of the vortex ring is shown. The cross-sections in the plane of the drawing correspond to the side view of the wake (*d*) and the one at right angles to this plane represents the front view of the wake (*c*). The direction of the vortex ring circulation is indicated by the arrows. The pictures were taken in a net cage (*a, b*) and in a large aquarium (*c, d*); the birds photographed were brambling (*b*) and chaffinch (*a, c, d*); the number of flashes per series was about 13 (*a*), 8 (*b*) and 7 (*c, d*); flash frequencies were 1 kHz (*a, b*) and about 0.75 kHz (*c, d*); visualisation was carried out with paper (*a, b*) and wood (*c, d*) dust.

The method involved multiple flash photography of moving small light particles forming a cloud through which the bird was forced to fly. Several visualising agents were tried but wood and paper dusts manufactured on a grindstone were most successful. Mean diameters of individual particles of both types of dust were 0.5–0.6 mm (paper dust had a more pronounced tendency to aggregate in flakes of a mean diameter of  $\sim 1.0$  mm), but average sinking velocities were different:  $0.5 \text{ m s}^{-1}$  in wood and  $0.2 \text{ m s}^{-1}$  in paper dust. Birds performed their short flights between two perches in a Plexiglass aquarium ( $2 \times 0.5 \times 1 \text{ m}$ ) and in a net cage ( $2.6 \times 0.6 \times 0.7 \text{ m}$ ). An electronic generator producing a series of flashes was designed for the study. The generator was used in a waiting regime and was triggered from one or two photorelays as the bird crossed an infrared beam. The frequency of flashes and their number per series were widely adjustable. Satisfactory results were obtained with frequencies of the order of 750–1,000 Hz and 6–8 flashes per series.

The experimental procedure was as follows. The room was darkened (only very faint illumination being retained) and the shutters of two photographic cameras were opened. Then a cloud of flow-visualisation particles was blown out with the aid of a long rubber tube from a container attached above the middle part of a bird's trajectory. At the same time the bird was flushed from the perch. The flying bird triggered the flash

generator and hence a wake photograph was produced. Cameras were then prepared for the next exposure and the cycle repeated.

In the photographs obtained the multiple images of individual particles clearly show directions and relative velocities of their movement in the plane of the paper. The faster a particle is moving the longer the segments of a broken line it produces. One can consider these lines as an approximation to the real trajectories of fluid particles. With the linear scale and flash frequencies known it is possible to calculate roughly a number of characteristic velocities in the plane of the wake flow field pictured.

To analyse the photographs obtained (Fig. 1) it is necessary to consider some peculiarities of the methods used. Photographic superposition of successive images causes a strong impression as if light objects, specifically dust particles, are always situated in front of dark ones. The bird itself moves relatively slowly, so its image is usually overexposed with few details visible—exposures being chosen to reproduce primarily the wake structure. Under the action of a centrifugal force the core parts of rotating bodies of air are free from visualising material. This causes accentuation of such structures, but it should be remembered that their apparent dimensions are also strongly dependent on the size and density of visualising particles. Finally, the

particle cloud was formed by the experimenter in such a way that it embraced only the wing of the bird remote from the observer, so that sections of the wake were produced on the photographs.

The two-dimensional longitudinal view of the bird wake conforms reasonably well to the reversed vortex street with a 'reactive' jet between the vortices—the pattern that was predicted long ago by theorists and then repeatedly reproduced in experiments with an oscillating aerofoil<sup>1</sup>. Analysis of the photographs also reveals that the spatial structure of the wake of an actively flying bird is represented by a series of thick and more or less deformed vortex rings with an intense and winding jet which passes through the rings' holes. Form and orientation (that is, axis inclination) of the vortex rings are variable because the photographs correspond to different stages of birds' short flight with different requirements on lift and thrust and unequal contribution by the ballistic component (the initial jump from the perch) at each stage.

The development of a vortex ring can be conceived in the following way. The upper part of the ring (if it is placed vertically) is formed by the starting vortices of both the wings at the beginning of their downstroke; these are extended on the sides of the ring, during the middle stages of the downstroke, by the wings' tip vortices. The lower part of the ring is formed by the stopping vortices shed from the wings in their lowest position at the bottom of the downstroke. The vortices generated by the left and right wing are closed against each other at the upper and lower points of the wing stroke. So a vortex ring is formed. In most if not all passerine birds all the aerodynamic work is known to be done only on the downstroke; on the upstroke the wings are folded and their interaction with the air is minimal<sup>2</sup>. This is why vortex rings in the wake of the finches studied here are produced only during the downstroke.

A recent theoretical model<sup>3,4</sup> has predicted the configuration of the vortex rings observed in these experiments as being the most realistic description of the wake of a flying bird, consistent with the unsteady regime of its wing beat. This model provides a framework for calculations of the power consumed in flight and for the quantification of the vortex distribution of the wake.

I thank Professor Sir James Lighthill for the kind attention he has given to this report and V. I. Petrowsky for designing the generator and helping to produce the photographs.

## Shoot height, weight and standing crop in relation to density of monospecific plant stands

DESPITE great differences in architecture and supporting tissue, monospecific stands of single-stemmed plants ranging in size from a moss to a tree follow a simple rule relating shoot dry weight and standing crop to density. We describe here an equation for this relationship which remains true for almost any fully occupied plant stand dominated by a single species.

Data were obtained, mostly from the literature<sup>1–19</sup>, for 65 stands of 29 different plant species (Table 1) ranging from mature midsummer shoots of annual and perennial non-woody species to saplings and full-sized trees. Figure 1a shows the

Fig. 1 The relationship of shoot dry weight and standing crop (a) and height (b) to density in monospecific stands of plants. Dashed boundary lines at 0.3  $\log_{10}$  intervals below and above the solid lines represent plants half and twice as large. Point B represents *Bolboschoenus maritimus*.

inverse, double logarithmic relationship of shoot dry weight ( $w$ , grammes) to density ( $d$ ,  $m^{-2}$ ). It is calculated as the reduced major axis<sup>20,21</sup>, because neither variable is truly dependent on the other, and has the form  $w = 9,670d^{-1.49}$  and the correlation coefficient  $r_{\log 10} = -0.987$ .

A simple geometric model, developed by Yoda *et al.*<sup>1</sup>, to explain intraspecific weight/density relationships during self-thinning of overcrowded stands of individual plant species, seems also to apply to interspecific weight/density relationships among diverse species, ranging in shoot weight over more than seven orders of magnitude and in shoot density over five orders of magnitude. The model is described as follows: (1) assume that available space is fully occupied (that is, that the leaf canopy is closed), and that the area occupied by a plant is proportional to the square of some linear dimension (for example, basal diameter or height); (2) then weight (or volume) per shoot will be proportional to the cube of the linear dimension; (3) weight per shoot is therefore proportional to the 3/2 power of the area occupied or to the -3/2 power of its reciprocal, which is density.

This exponent of  $-1.5$  is very close to that observed in Fig. 1a ( $-1.49$ ), which therefore appears to fit the suggested model despite major differences in plant architecture (for example, *Polytrichum*, *Pteridium*, *Carex*, *Typha*, *Phragmites*, *Ambrosia*, *Betula*, *Abies*), and in the nature of supporting tissues, with a large component of parenchyma in some species (for example, *Eleocharis*, vegetative shoots of *Typha*) and of sclerenchyma in others (*Abies*, *Betula*).

The relationship may be followed further by examining the ranges of shoot height and weight (Table 2). The rules of the simple geometric model dictate that the range for  $\log_{10}$  height ought theoretically to be half the range for  $\log_{10}$  density, whereas the range for  $\log_{10}$  weight ought to be 1.5 times the range for  $\log_{10}$  density. The observed ranges are in good agreement with the model, being within 7% of the theoretical range for height, and within 2% of the theoretical range for weight. Conformity would probably be greater if height data were available for the largest *Abies sachalinensis*. It is 6.5 times the weight of *Taxodium distichum*, the largest plant for which height data are available. According to the model, 6.5 times greater weight implies 1.87 times greater height, and an increase of 0.27 in the  $\log_{10}$  height range. Adding 0.27 to 2.44 gives 2.71, within 4% of the theoretical height range for all 27 species.

The relationship of shoot height ( $h$ , cm) to density ( $d$ ) of 15 species in 19 stands is shown in Fig. 1b, and is given by the reduced major axis,  $h = 970d^{-0.443}$ . The correlation coefficient,  $r_{\log 10} = -0.902$ . Thus, density explains only 81% of the variance in shoot height, as compared with 98% of the variance in weight for the same 19 stands. Marked architectural differences are reflected in the ratios of height to cube-root of dry weight among the different species. Ratios for seven species of *Carex* range from 67 to 130, whereas two species of *Typha* have ratios of 40 and 68. Three stands of *Phragmites communis* range from 76 to 93. Trees exhibit lower ratios, 39 and 26 for *Pinus silvestris* and 26 for *Taxodium distichum*. The moss *Polytrichum commune* has the lowest ratio, at 19.

\*Other species accounted only for a few % of above-ground standing crop and less than 10% in all measured cases.

†Data for both weight and height were available.

The weight/density relationship within a monospecific plant stand undergoing competitive self-thinning is generally characterised<sup>1</sup> by a negative exponent of  $-1.5$ . Different species are expected<sup>1,22</sup> to exhibit distinct differences in the constant  $C$  of the equation  $w = Cd^{-1.5}$ . Several species should thus yield a family of curves, all with negative exponents near  $-1.5$ , but with different values for the constant  $C$  presumably reflecting differences in plant architecture. However, within the limits of variability normally observed for such an inverse power-law relationship, most species fit reasonably well to the solid line in Fig. 1a, defined by a single value (9,670) of the constant  $C$ . Three-quarters of the 65 plant stands in Fig. 1a lie within the

dashed boundary lines shown 0.3  $\log_{10}$  intervals below and above the fitted solid line. These boundary lines ( $C = 4,900$  and 19,500 respectively) represent shoots one-half and twice as large as those which fit the equation given earlier. Moreover, data for many individual species reveal a variability at least as great as that represented by the dashed boundary lines. Data from laboratory experiments may be similarly variable. Two populations of *Helianthus annuus* allowed to self-thin at full light intensity<sup>22</sup> exhibited  $C$  values of 6,920 and 91,200 respectively, and regression exponents of  $-1.33$  and  $-1.84$ . The clumped distribution of many plant shoots and the often logarithmic frequency distribution of shoot sizes in overcrowded stands<sup>1</sup> contribute greatly to the substantial variability.

Table 2 The ranges of height\*, density† and weight† for the plant shoots in Fig. 1

	Minimum	Maximum	$\log_{10}$ range	
			Actual	Theoretical
Height (cm)	5.0	$1.39 \times 10^3$	2.44	2.62
Density ( $m^{-2}$ )	0.079	$1.38 \times 10^4$	5.24	—
Dry weight (g)	0.019	$1.07 \times 10^6$	7.75	7.86

\*19 stands, 15 species. †65 stands, 27 species.

Architecturally diverse species overlap considerably, and where deviations from the reduced major axis occur they do not seem to be related in any consistent way to differences in plant architecture or in the nature of the supporting tissues. A number of self-thinning curves in the literature<sup>1,22</sup> also conform rather well to the relationship shown in Fig. 1a, especially if reasonable corrections are made for below-ground material of whole plants. Even if more detailed study reveals systematic variations in the constant  $C$  which can be related to differences in plant architecture, Fig. 1a suggests that its values will lie within a fairly narrow range, and mostly between half and twice the value reported here.

Two species, *Chenopodium album*<sup>1</sup> and *Bolboschoenus nigricans* (B in Fig. 1a), appear to deviate substantially from the relationship reported here. The deviation of *Chenopodium* is particularly striking because of the conformity of a similar weed, *Amaranthus retroflexus*<sup>1</sup>. However, according to one of the authors (T. Kira), their *Chenopodium* data were for fresh weight, others were for dry weight. *Bolboschoenus* (= *Scirpus*) *maritimus*, marked B in Fig. 1a, lies well below the reduced major axis. This rhizomatous species colonises open water, and probably had not developed a closed canopy. The relationship will also break down where aridity and cold prevent development of a complete plant cover, as in deserts and tundra.

Self-thinning is not always characteristic of monospecific stands of plants in nature, particularly in uncrowded situations. The exponent in the weight/density relationship is generally close to  $-1.0$  in such cases, so that standing crop per unit area is independent of density. This is the 'Law of Constant Final Yield'<sup>23</sup> and this holds for stands of *Taxodium distichum* in Georgia<sup>17</sup> and *Phragmites communis* in Czechoslovakia<sup>12</sup>. The reduced major axes for both species lie close, although at an angle, to their respective short segments of the fitted line in Fig. 1a. Apparently this line sets an approximate upper limit to the mean size of plant shoots at any given density, whether or not self-thinning is taking place.

The negative slope in Fig. 1a obviously reflects structural constraints, with a less dense plant spacing allowing a larger basal area for stem support, and hence a greater ultimate height and mass. This structural explanation might be thought to have an underlying basis in the physiological balance between respiration, a function of shoot weight, and photosynthesis, a function of leaf area. In such a case, shoot weight ought to be

closely related to leaf area index. However, leaf area indices calculated from data compiled by R. H. Whittaker<sup>24</sup> show little difference in communities with very different shoot densities and sizes. For example, temperate and tropical evergreen and deciduous forests exhibit mean indices between 5 and 12 m<sup>2</sup> m<sup>-2</sup>, as compared to indices of 3.6 for temperate grasslands and 7.0 for swamps and marshes. Grassland and wetland communities have far smaller shoot weights and greater shoot densities than forests. Moreover, fourteen Czechoslovak stands of *Phragmites communis*<sup>12</sup> exhibit no relationship of leaf area index, which ranges from 2.4 to 6.3, to either shoot weight or density, which correlate strongly with one another ( $r_{\log 10} = -0.91$ ). White<sup>25</sup> discusses the point in more detail.

It follows from the weight/density relationship in Fig. 1a that large plants growing at low density yield a larger above-ground standing crop than small plants at high density, with  $wd = 9,670d^{-0.49}$ . This relationship is shown as a dash-dot line in Fig. 1a. It can be seen that standing crop at a density of 0.1 shoots m<sup>-2</sup> (characteristic of a large tree) is 26,000 g m<sup>-2</sup>, whereas at a density of 10,000 shoots m<sup>-2</sup> (characteristic of a large moss), it is 120 g m<sup>-2</sup>. Only widely spaced plants, which can develop a large basal area and so grow to great heights, are able to accumulate large amounts of biomass. This is so obvious as to be a truism. The remarkable fact is that a single, simple rule relating shoot weight and standing crop to density should apply over so many orders of magnitude and to plants as diverse in their architecture as mosses, ferns, gymnosperms, monocotyledons and dicotyledons.

After submitting this article I learned from J. L. Harper that a similar relationship was described at the Twelfth International Botanical Congress in Leningrad by J. White, who subsequently informed me that it will be dealt with further in a forthcoming publication.

I thank E. C. Abbe, W. L. Koukkari, E. G. and D. J. McLaughlin, P. A. Morrow, D. C. Pratt and A. van der Valk for their comments, and E. J. Cushing for a detailed review. A. van der Valk and W. H. Schlesinger provided data in advance of publication. J. White transmitted T. Kira's explanation of the aberrant *Chenopodium* data, and informed me of his 1977 and forthcoming papers.

## Parasite pathogenicity and the depression of host population equilibria

THE use of pathogens as agents for the biological control of pest species has increased rapidly in recent years with the realisation that chemical pesticides are not the panacea they were once thought to be<sup>1-6</sup>. The selection of a suitable parasite is often based on the assumption that highly pathogenic organisms will be most effective in minimising pest population growth<sup>6-8</sup>. Recent theoretical studies of the dynamics of host-parasite associations provide a template for testing this assumption<sup>9-12</sup>. This paper examines the relationship between parasite pathogenicity, as measured by the severity of the pathogen's influence on host survival, and the consequent depression of the host population from the size it would have achieved in the absence of infection. The maximum degree of depression is achieved by direct life cycle parasites of moderate to low pathogenicity, a prediction which has important implications for the use of pathogens as biological control agents. In agreement with traditional beliefs<sup>13,14</sup>, theory suggests that highly pathogenic species will cause their own extinction but not that of their host. The relationship between population depression and host reproductive potential is shown to be critically dependent on the biological characteristics of the pathogen.

Parasites can be divided into two main classes. Microparasites (viruses, bacteria, protozoans) are characterised by small size, short generation times, extremely high rates of direct reproduction within the host, and a tendency to induce lasting immunity to re-infection in those hosts that survive initial infection<sup>15</sup>. The duration of infection is typically short in relation to the expected lifespan of the host, and thus is of a transient nature (there are exceptions to this general trend, as shown, for example, by herpes simplex virus<sup>15</sup> and the slow viruses<sup>16</sup>). Macroparasites (parasitic helminths and arthropods) have much longer generation times, and direct multiplication within or on the host is either absent or occurs at a low rate compared with that of microparasites.

Such immune responses as are elicited by these metazoans tend to depend on the number of parasites present in a given host and to be of relatively short duration relative to the expected lifespan of the host<sup>17-19</sup>. Macroparasitic infections therefore tend to be of a lasting nature, as the hosts are susceptible to continued re-infection.

Both microparasites and macroparasites may complete their life cycles by passing from one host to the next either directly or indirectly via one or more intermediate host species. Pathogens which have been used in biological control<sup>1-3</sup>, and those whose potential is now being investigated<sup>4-8</sup>, all exhibit direct life cycles (various viruses, bacteria, protozoa and nematodes).

The influence of parasite pathogenicity (*per capita* rate of parasite-induced host mortality) on the dynamics of host population growth may be explored by means of population models framed in differential equations. The mathematical theory of the dynamics of microparasitic infectious diseases, as recently reviewed by Bailey<sup>20</sup>, is largely based on compartmental models which delineate susceptible, infected and immune categories of hosts (containing, respectively,  $x$ ,  $y$  and  $z$  numbers of hosts). The model used to examine the dynamics of microparasitic infections differs from standard epidemiological models in assuming that the total number of hosts,  $H = x + y + z$ , is not treated as some independently set constant, but is assumed to be a variable determined by both the dynamics of the disease and the natural *per capita* birth rate,  $a$ , and death rate,  $b$ , of the host. It is also assumed that in the absence of infection the disease-free population grows logistically<sup>21</sup> to an environmental carrying capacity,  $K$ , where  $K = (a - b)/\beta$  (the constant  $\beta$  measures the severity of density-dependent constraints on population growth). The system of equations for susceptible  $x$ , infected  $y$  and immune  $z$

**Fig. 1** Microparasitic infection model. Following conventional lines, the rate at which hosts acquire infection is assumed to be proportional to the number of encounters between susceptible and infected hosts, being  $\Lambda xy$ , where  $\Lambda$  is a transmission coefficient<sup>20</sup>. The mortality rate of infected hosts is taken to be  $b + \hat{\alpha}$ , with  $\hat{\alpha}$  representing the mortality caused by the disease; there is also a recovery rate from infection,  $v$ . Recovered hosts are assumed to be initially immune, but this immunity can be lost at a rate  $\gamma$  (for permanent immunity  $\gamma = 0$ ). These assumptions lead to the following equations:  $dx/dt = aH - (b + \beta H)x - \Lambda xy + \gamma z$ ,  $dy/dt = \Lambda xy - (b + \beta H)y - \hat{\alpha}y - v y$ ,  $dz/dt = v y - (b + \beta H)z - \gamma z$ . The construction of these equations follows conventional lines<sup>20</sup> (with the parameters  $a$ ,  $b$  and  $\beta$  as defined in the main text) except for the inclusion of a *per capita* density-dependent host mortality rate  $(b + \beta H)$ <sup>21</sup>. The sum of the three equations for  $x$ ,  $y$  and  $z$  yields:  $dH/dt = (a - b - \beta H)H - \hat{\alpha}y$ , equation (1). Provided  $(a - b)$  is positive, the model yields locally stable equilibria. If host density,  $H$ , is less than a threshold value,  $H_T$ , where  $H_T = (b + \hat{\alpha} + v)/(\Lambda - \beta)$ , then after the introduction of infected hosts into the population,  $y$  will initially decrease and  $x$  increase. However, once  $x$  exceeds  $H_T$ , then  $y$  will increase and the system will converge (steadily or with damped oscillations) on one of two types of stable equilibrium state. Stable co-existence of host and parasite, where  $H^* < K$  and  $y^* > 0$ , will result provided  $\Lambda > \beta[1 + (b + \hat{\alpha} + v)/(a - b)]$ . If this condition is not satisfied the parasite fails to co-exist and  $H^* = K$  and  $y^* = 0$ . *a*, The influence of parasite pathogenicity,  $\hat{\alpha}$ , and the natural intrinsic growth rate of the host population  $r$ , where  $r = a - b$ , on the degree of host population depression  $d$ , where  $d = 1 - H^*/K$ . Parameter values of the model are as follows:  $\beta = 0.01$ ,  $\Lambda = 0.1$ ,  $\gamma = 0.05$ ,  $v = 0.5$ . *b*, The influence of  $\hat{\alpha}$  and  $r$  on the equilibrium proportion of infected hosts,  $y^*/H^*$ . Parameter values as for *a*.

hosts and their dynamical properties are detailed in the legend to Fig. 1. The model has two distinct patterns of population behaviour, namely (1) the disease persists and regulates the host population at a locally stable equilibrium  $H^*$ , where  $H^* < K$ , and  $y^* > 0$ ; (2) the infection is not maintained within the host population and a stable disease-free equilibrium results where  $H^* = K$  and  $y^* = 0$ .

The relationship between parasite pathogenicity, measured by  $\hat{\alpha}$ , the *per capita* rate of disease-induced mortality in the infected class of hosts, and the degree of depression of the host population equilibrium,  $d$ , where  $d = 1 - H^*/K$  (varying

between 0 and 1), is shown in Fig. 1*a* for various values of  $r$ , the natural intrinsic growth rate of the host population ( $r = a - b$ ). For a fixed value of  $r$ , the maximum degree of depression is achieved by parasites of moderate to low pathogenicity. Increased rates of parasite-induced host mortality result in a greater degree of host population depression until the rate of loss of infected hosts begins to have a detrimental effect on the efficiency of disease transmission. When the level of pathogenicity is very high, infected hosts die before effective transmission is achieved and the disease is thus unable to persist within the host population ( $y^* \rightarrow 0$ ,  $H^* \rightarrow K$ ). In brief, highly pathogenic organisms are likely to cause their own extinction but not that of their host. These conclusions withstand a variety of changes in model structure. Most importantly, if a totally immune category of hosts is absent, recovered hosts passing directly back to the susceptible class (as may often be the case with microparasitic infections of arthropods), a pattern emerges which is similar to that shown in Fig. 1.

Macroparasites with direct life cycles tend to produce persistent infections where the pathogenicity to the host, the rate of production of transmission stages and any resistance of the host to further infection all typically depend on the number of parasites present in a given host<sup>11,17-19,22</sup>. A crude division of the host population into susceptible infected and immune classes is therefore inappropriate and a description of the dynamics must deal with the full probability distribution of parasites within the host population. Anderson and May<sup>9</sup> have studied the dynamics of macroparasitic diseases with the aid of three differential equations for the number of hosts  $H$ , parasites  $P$ , and free-living infective stages  $W$ , which incorporate certain statistical moments of the distribution of parasite numbers per host. Parasite pathogenicity is measured by a parameter,  $\alpha$ , which defines the disease induced *per capita* host death rate, per parasite, as a large amount of empirical evidence suggests that the rate of host mortality is proportional to parasite burden in a given host<sup>9,11,22</sup>.

A model based on the work of Anderson and May<sup>9</sup> but incorporating the assumption that in the absence of infection ( $P = 0$ ) the host population grows in a logistic manner as defined in equation (1) (the details of the model are given in the legend to Fig. 2), predicts a similar relationship between parasite pathogenicity,  $\alpha$ , and host population depression,  $d$  (Fig. 2), to that derived for microparasitic infections (Fig. 1). A further similarity in the predictions of the two models is shown in Figs 1*b* and 2*b*. Increased pathogenicity results in a decrease in both the proportion of infected hosts ( $y^*/H^*$ , microparasitic infections) and the mean parasite burden ( $P^*/H^*$ , macroparasitic infections). Both models suggest that observed levels of prevalence and intensity of infection within host populations in natural habitats will closely reflect parasite pathogenicity, a prediction supported by empirical evidence<sup>23</sup>.

In contrast to these similarities, the impact of high rates of host population growth in the macroparasitic infection model is to lessen the degree of depression relative to the disease-free equilibrium value  $K$ , whereas the exact converse is predicted by the microparasite model. The explanation of this paradox lies in the ability of microparasites to colonise a host by direct multiplication within the host. The rate of establishment of new colonies in uninfected hosts is therefore enhanced by high host birth rates which continually replenish the stock of susceptible individuals. High rates of establishment increase the proportion of infected hosts in the population and thus increase the degree of population depression. Experimental studies of viral and bacterial infections in mouse populations clearly illustrate this principle<sup>24</sup>.

In contrast, the population growth of macroparasites, which do not tend to exhibit direct multiplication, is dependent on the gradual accumulation of new infections within individual hosts and not on the input of susceptible individuals to the host population. High host birth rates tend to offset the mortalities caused by infections and hence decrease the degree of host population depression. Substantial depression of host popu-

**Fig. 2** Macroparasitic infection model. The framework of the macroparasitic model is based on the work of Anderson and May<sup>9,11</sup>, where the three equations for the population of hosts  $H$ , parasites  $P$ , and infective stages  $W$  are as follows:  $dH/dt = (a - b - \beta H)H - \alpha P$ ,  $dP/dt = \Lambda WH - (\mu + b + \alpha + \beta H)P - (\mu + \alpha)(k + 1)P^2/(kH)$ ,  $dW/dt = \lambda P - cW - \Lambda WH$ . The host birth and death rates  $a$  and  $b$  are as defined earlier for the microparasite model, as is the transmission parameter  $\Lambda$  (hosts acquire individual parasites at a rate proportional to the number of contacts between hosts and parasite infective stages,  $\Lambda WH$ ) and the density-dependent host mortality rate,  $b + \beta H$ . The parasite-induced host death rate is assumed to be linearly proportional to the parasite burden in a given host and to occur at a rate  $\alpha$  per parasite. The parasites are distributed as a negative binomial distribution with parameter  $k$ ;  $\mu$  is the natural mortality rate of adult parasites, the net rate being dependent on the density of parasites within an individual host;  $\lambda$  is the rate of production of infective stages by an adult parasite, and  $c$  is the death rate of these infective stages. The empirical basis of these equations has been described in detail elsewhere<sup>9-11</sup>. Provided  $(a - b)$  is positive, the model yields locally stable equilibria. If host density  $H$  is less than a threshold value  $H_T$ , where  $H_T = c(\mu + a + \alpha)/[\Lambda(\lambda - \mu - a - \alpha)]$ , then the parasite cannot become established ( $dP/dt < 0$ ). However, if  $H > H_T$ , provided  $\lambda - (a + \mu + \alpha) > c\beta(a + \mu + \alpha)/[\Lambda(a - b)]$ , the infection will become established and the equilibrium states  $H^* < K$  and  $P^* > 0$  are locally stable. If this condition is not satisfied the parasite fails to persist and  $H^* = K$  and  $P^* = 0$ . *a*, The influence of parasite pathogenicity  $\alpha$  and the natural intrinsic growth rate of the host population  $r$  on the degree of host population depression  $d$ . Parameter values of the model are as follows:  $\beta = 0.01$ ,  $\lambda = 8$ ,  $\mu = 0.1$ ,  $k = 1.0$ ,  $c = 2.5$ ,  $\Lambda = 0.5$ . *b*, The influence of  $\alpha$  and  $r$  on the equilibrium mean parasite burden per host,  $P^*/H^*$ . Parameter values as for *a*.

lations with high reproductive potentials may be achieved by macroparasites with the ability to produce large numbers of transmission stages to ensure the rapid accumulation of parasites within individual hosts.

The most important prediction of both models is related to the use of parasites as biological control agents; direct life-cycle

micro- and macroparasites of low to moderate pathogenicity are the most effective suppressors of host population growth. Very pathogenic organisms are likely to cause their own extinction but not that of their host. These conclusions seem to be reliable as they are derived independently from two mathematical models of very different structure.

Current practice is to select highly pathogenic organisms for the biological control of pest species<sup>1-8</sup>. Such pathogens may cause high initial mortality within the pest population in a manner analogous to a single application of a chemical pesticide. However, in the absence of repeated introductions they are unlikely to achieve maximum and lasting depression of the pest population.

I thank Michael Hassel, John Lawton and Robert May for helpful discussions.

## The Stiles-Crawford hue shift following photopigment depletion

THE colour of a light is determined by such factors as its dominant wavelength, luminance, colorimetric purity, locus of retinal stimulation, surround chromaticity and preceding adapting field. Stiles and Crawford<sup>1</sup> were first to note that the position at which a small pencil of light enters the pupil also affects the light's colour. In general, light that enters through the centre of the pupil is seen as brighter than the same light impinging on the same retinal area but passing through the periphery of the pupil. This is known as the Stiles-Crawford effect of the first kind (S-C-I). It has been demonstrated that this effect is due to the directional sensitivity of the receptors<sup>2-4</sup> and is much more pronounced in cones than in rods<sup>5-8</sup>. Stiles<sup>9</sup> also showed that two monochromatic lights of the same wavelength, one passing through the centre of the pupil (on-axis), the other entering through the periphery (off-axis), will differ in hue even after they are equated for brightness. (There is also a small change in

**Fig. 1** S-C II for subject BW.  $\Delta\lambda$  represents the shift required to bring an off-axis light to the same wavelength as an on-axis light after both lights have been matched in hue and brightness. Circles are means of two or three separately determined points of subjective equality. Vertical lines are the 5–95% range estimated from the psychometric functions used in deriving the means. ●, No-bleach condition; ○, high-bleach condition. The horizontal dashed line is the predicted result for the high-bleach condition based on the self-screening model.

saturation that becomes almost negligible at the long-wavelength end of the spectrum.) This is known as the Stiles-Crawford effect of the second kind (S-C II). For example, to match in hue an on-axis light of 610 nm an observer might require an off-axis light of 605 nm. The direction and magnitude of this hue shift varies with the wavelength of the on-axis light (Fig. 1). We have measured S-C II in conditions of varying levels of bleached photopigment. An explanation of the effect based on the absorbance of the photopigment can account for much but not all of the data. For the long-wavelength end of the spectrum, when the photopigment is significantly depleted, some other factor must have a role in mediating this effect.

Related to S-C II is the finding that the proportion of mixed red and green light required to match a yellow light (a metameric match) is different depending on where in the pupil the lights enter<sup>10</sup>. This upset in the metameric match must reflect the change in the shape of the spectral sensitivity curve of at least one of the three cone mechanisms when the light-entry position is changed. An altered shape in the spectral sensitivity curve of at least one of the cone systems can also account for S-C II.

Two hypotheses, that differ in their model of how light interacts with photoreceptors, have been proposed to explain these wavelength-dependent Stiles-Crawford effects. In so doing, these hypotheses have addressed the question of what it is that determines the spectral sensitivity of the cones, which is the fundamental property of the visual system on which our colour perception is based.

The waveguide hypothesis<sup>11–13</sup>, based in part on physical optics, proposes that as the diameters of the photoreceptors are only slightly greater than the wavelength of light, the receptors act as dielectric (optical) waveguides. Light is propagated through and around an optical waveguide in non-uniform patterns of energy known as modal patterns. The amount of light travelling inside the guide is given in part by the kind of modal pattern produced. Also the amount of light available for absorption by the photopigment varies with the wavelength of the incident light and the angle of incidence. These, of course, are the two independent variables associated with S-C II. It is possible to derive a theoretical curve that closely matches the one seen connecting the filled circles in Fig. 1 by varying the parameters of the waveguide that determine its sensitivity (for example, refractive indices of the receptor and its surrounding medium, outer segment diameter, length and shape)<sup>14,15</sup>.

According to the self-screening hypothesis<sup>16–18</sup>, which is based solely on geometric optics, light that enters through the pupil off-axis passes through less photopigment than on-axis light because of the former's oblique angle of incidence at the receptor layer. Such a shortening of the pathlength that the light takes through the pigment is equivalent to a reduction in the absorbance of the pigment. This follows from the Beer-Lambert law as does the fact that such a reduction has the effect of narrowing the spectral sensitivity curve of the cone system(s) involved. Self-screening has been shown to provide a reasonably good quantitative account of S-C II, if it is assumed that the absorbance of the photopigment(s) is about 0.5 or greater<sup>18</sup>. Based on direct<sup>19,20</sup> and indirect<sup>17</sup> estimates of the absorbance of human cone photopigments coupled with the assumption that passing light through the periphery of the pupil effectively shortens the pathlength, self-screening must to some extent be occurring and therefore must contribute at least in part to S-C II. Furthermore, self-screening provides a model with fewer assumptions and fewer free parameters than the waveguide model. We thus decided to test the generality of the self-screening model to see if S-C II could be accounted for entirely in terms of geometric optics and the absorption properties of photopigments.

In accord with the Beer-Lambert law, the lower the initial absorbance of a pigment, the smaller will be the range over which the absorbance can further be reduced. Thus, inherent in the self-screening model is the prediction that the magnitude of S-C II will be directly proportional to the initial absorbance of the photopigment. In the extreme case, when nearly all the photopigment is depleted, no measurable effect should be obtained.

It is possible to manipulate the initial absorbance of the photopigment by exposing the eye to an adapting light of a certain intensity. Such a bleaching light renders a given amount of pigment incapable of any further absorption of light. The reduction in concentration of available quantum-catching pigment thereby reduces the absorbance of the photopigment.

In our experiment, we measured S-C II in a no-bleach and a high-bleach condition in three subjects. Each subject was presented with two juxtaposed, circular fields each 20' in visual angle. The stimuli were presented in maxwellian view to one eye and were seen foveally. The source images, focused in the plane of the pupil, were 1 mm in diameter. One field, the standard, was

**Fig. 2** S-C II at 610 nm as a function of the level of bleached photopigment for subject BW. The points are derived as described in Fig. 1, except that each point represents the result from a single session. Lightly dashed line shows the predicted result for bleaching levels above 40% based on the self-screening model. Below 40% the self-screening prediction and the obtained results coincide. Predictions are based on the receptor primaries of Vos and Walraven<sup>24</sup> assuming an absorbance of 0.5 for each pigment. It is also assumed that both pigments are bleached at the same rate by the white adapting field.

fixed in wavelength for a given session and entered through the pupil on-axis. The other field was varied around the standard in steps of 2 nm and entered through the pupil off-axis. (The position in the pupil that yields the peak luminous efficiency of a light is not always the centre. Therefore, we measured S-C I along the horizontal meridian to determine the pupillary position for each subject that represented the peak of his S-C I curve. For all subjects, the peak occurred within 1 mm of the geometric centre of the pupil. This was termed the on-axis condition. The off-axis condition was achieved by displacing the source image 3 mm to the opposite side of the pupil along the horizontal meridian.) The subject was required to state whether the variable field appeared to be a hue associated with a wavelength longer or shorter than the wavelength associated with the hue of the standard. Before each judgment, the subject matched the two fields in brightness. Residual differences in saturation, which were for the most part small, were disregarded. The luminances of the test fields were set by the subject to the lowest level possible in making a perfect match. Each wavelength chosen for the variable field was repeated five times. From the resulting psychometric function, the point of subjective equality could be determined. This was done for eight standards: 470, 490, 508, 525, 540, 578, 610 and 630 nm. All lights, except the white adapting field, were monochromatic (Bausch and Lomb grating monochromators, focal length, 0.5 m) with half-band widths of 3 nm. Each standard was repeated in a second session. If the results from the first and second session differed by more than 3 nm, a third session was included. For the high-bleach condition, following a 4-min exposure to a 5°, xenon-white adapting field that was calculated to bleach 88% of the mid- and long-wavelength sensitive cone pigments, each subject was presented with the following sequence of stimuli: a 2-s dark interval, a 1-s exposure of the test fields, a 10-s presentation of the bleaching field. This cycle, which maintained the percentage of pigment bleached at a constant level, continued for the duration of the session (about 0.5 h). The percentage of pigment bleached was calculated from Rushton and Henry's reflection densitometry measurements and pigment kinetic equations<sup>21</sup>. For the no-bleach condition, the subjects dark-adapted for 10 min and were then presented the test fields for 1 s every 4 s.

Figure 1 (filled circles) shows results for one subject for the no-bleach condition and are similar to the findings of others<sup>9,16,18</sup>. The other subjects' data agree with those shown here. For example, when an on-axis light is set to 610 nm, the subject requires that an off-axis beam of light be approximately 605 nm for the two lights to match. Figure 1 (unfilled circles) are the results for the high-bleach condition. For this condition, the self-screening prediction (no hue shift) is represented by the horizontal, dashed line. While the data roughly agree with the prediction up to 540 nm, at longer wavelengths the empirical findings depart significantly from the theoretical curve. With 610 nm as an example again, in the no-bleach condition, an off-axis light of this wavelength appeared too red compared with an on-axis light of the same wavelength. In the high-bleach condition, a 610-nm, off-axis light appeared far too yellow when compared with a 610-nm, on-axis light.

We examined 610 nm at intermediate bleaching levels (Fig. 2). Self-screening predicts that as the percentage of bleached pigment increases, the magnitude of the effect should decrease until, finally, at close to a 100% bleach, the effect should be unmeasurable. The data are in agreement with the self-screening prediction for low and intermediate bleaching levels, but, above a 65% bleach, theory and data are discrepant. Our results for the long-wavelength end of the spectrum suggest that at high bleaching levels a factor other than self-screening, such as waveguide effects, must be invoked to account for S-C II. This is consistent with Weale's<sup>22</sup> conclusion that long-wavelength light is treated preferentially in terms of the physical optics of the receptors. It might be that lights used to bleach a substantial portion of photopigment alter receptor properties in such a way as to increase a waveguide effect.

In conclusion, the present data indicate that a self-screening model can adequately account for S-C II when the eye is adapted to lights that bleach up to about 65% of the photopigment. This means that in such light-adapting conditions, the spectral sensitivity of each of the individual cone mechanisms is determined largely or solely by the absorption characteristics of their respective photopigments and the geometric optical properties of the receptors. However, when the photopigment is substantially depleted, possible waveguide effects of the receptors are revealed and have a significant role in determining spectral sensitivity.

## Estimating maximum limits to mutagenic potency from cytotoxic potency

RAPID and reliable screening methods are required for identifying environmental mutagens and estimating their mutagenic potency in preparation for use of more elaborate tests to assess the genetic risk to man. Many compounds are effectively screened by *in vitro* mutagenesis assays using either bacterial or mammalian cells. Although tests with mammalian cells are not as rapid and inexpensive as microbial assays, they are needed to confirm and extend the bacterial results, and probably provide a better assessment of potential risk to humans than do microbial tests. However, the screening of all potential mutagens with mammalian cell mutagenicity assays, although desirable, does not seem feasible unless, as we propose, test compounds are first pre-screened on the basis of their cytotoxic potency. On theoretical grounds, one expects a certain minimum cytotoxic potency to correlate with mutagenic potency, particularly when the latter is measured using forward mutations that result in inactive gene products. Specifically, cells cannot divide unless a substantial fraction of their genome is functionally intact; mutagenic agents should thus be obligatory cytotoxic agents, with a given mutagenicity conferring a certain irreducible cyto-

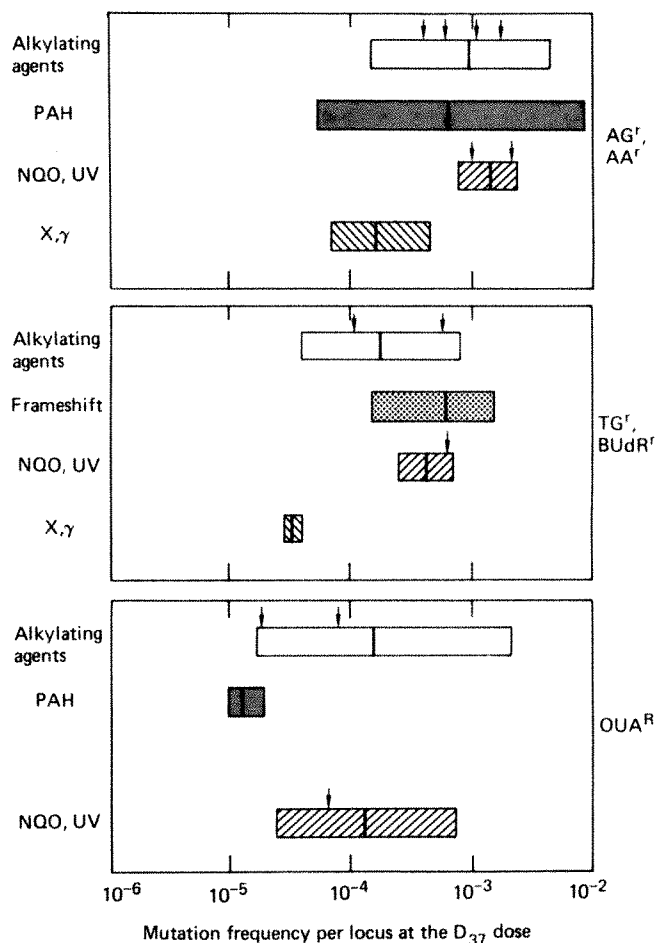

**Fig. 1** The relationship between induced mutation frequency per viable cell (MF) per unit exposure dose (molar) and the reciprocal of  $D_{37}$  (M), that is, the dose required to kill 63% of the initial cell population. Killing is defined as the inability of a cell to undergo continued cell division *in vitro* resulting in a viable cell colony. The  $D_{37}$  values were estimated from (1) authors' precise survival responses; (2) computer fits in ref. 14; (3) published tabular data (occasionally over limited dose ranges). In some cases, the values are approximate but individual estimates generally vary no more than  $\pm 20\%$  and never more than  $\pm 50\%$  (in two cases). Mutation frequency data usually included at least two dose points in the most linear range, except for a few reports having only limited data where a single dose and zero dose (spontaneous frequency) were used. The data included in this plot are those for mutations at the *hprt* locus (hypoxanthine-guanine phosphoribosyltransferase, EC 2.4.2.7), the *aprt* locus (adenine phosphoribosyltransferase, EC 2.4.2.8), and the *tk* locus (thymidine kinase, EC 2.7.1.75). Results in Chinese hamster ovary cells<sup>7-14</sup> ( $n = 25$ ), V79 hamster cells<sup>15-27</sup> ( $n = 18$ ), L5178Y mouse lymphoma cells<sup>28-31</sup> ( $n = 4$ ), normal human diploid fibroblasts<sup>32-38</sup> ( $n = 9$ ) and human lymphoblasts<sup>39,40</sup> ( $n = 4$ ) were combined and expressed as the induced frequency of mutants resistant to azaguanine, AG<sup>r</sup> ( $n = 27$ ); thioguanine, TG<sup>r</sup> ( $n = 27$ ); azaadenine, AA<sup>r</sup> ( $n = 4$ ); bromodeoxyuridine, BUdR<sup>r</sup> ( $n = 2$ ). Abbreviations for the mutagens are given in Table 1. The linear regression line is given by the equation  $\log MF/M = 1.03 (-\log D_{37}) - 3.49$ , with a correlation coefficient of 0.93. The dotted lines represent boundaries of the 95% confidence band for Y data points estimated from X. The physical mutagens were entered on the figure after calculating their potencies relative to EMS, based on the ratios of the number of lesions induced in the DNA of a cell at the  $D_{37}$  doses (UV-induced dimers<sup>41</sup> and total ionisation lesions<sup>5,6</sup>) to the number of alkylations<sup>42</sup> induced by EMS at its  $D_{37}$ . The 'molar equivalent  $D_{37}$ ' values were obtained by multiplying the  $D_{37}$  for EMS ( $6 \times 10^{-3}$  M) by the potency ratios for UV (0.18) and ionising radiation ( $1.4 \times 10^{-3}$ ). The 'molar equivalent mutation frequencies' were obtained by multiplying the geometric means of the observed mutation frequencies per  $D_{37}$  for UV and ionising radiation by the respective molar equivalent  $D_{37}$  values. The calculated parameters were added to the graph, but were not included in the regression calculation. The lower detection limit of the assays (stippled area) was estimated, assuming that (1) at frequencies below  $10^{-5}$  induced mutations per viable cell, statistically significant determinations of MF are generally not practical, and (2) the maximum feasible exposure dose is usually  $\leq 10$ -fold higher than the  $D_{37}$  concentration.

toxicity. We show here that the cytotoxic potency of 22 chemical mutagens is highly correlated with their mutagenic potency as assayed in five rodent and human *in vitro* cell systems. This relationship implies that the maximum potential mutagenic potency of such compounds may be reliably estimated from rapid and straightforward measurements of their cytotoxic potency, the latter defined as the failure of cultured cells to undergo continued cell division. The estimate is necessarily a maximum one, as an agent may exert cytotoxic effects by pathways independent of its mutagenic action.

A correlation between cell survival and mutagenic response has been noted for ionising radiation mutagenesis<sup>1</sup> and also seems to be applicable to ultraviolet radiation and certain chemicals<sup>2-4</sup>. Roberts *et al.* have discussed the molecular aspects of cellular lethality and mutagenesis in terms of damage to DNA<sup>5,6</sup>. To test this relationship further, we have compiled data on the cytotoxicity and mutagenicity of the 24 chemical and physical mutagens listed in Table 1. As the measure of cytotoxic

potency, we have used the  $D_{37}$  unit of survival, defined here as the dose required to kill approximately 63% of the initial cell population. Unlike  $D_0$ , estimation of  $D_{37}$  is usually possible from the limited survival data that accompany published mutation frequencies;  $D_{37}$  generally measures survival within the linear portion of the dose response for mutation (lower survivals are frequently out of the linear mutation range). Moreover, this parameter reflects differences in repair capability or fidelity that may influence both toxicity and mutagenicity.

Figure 1 compares the frequency of forward mutations induced per applied dose with the reciprocal of the molar dose required for  $D_{37}$  survival in three rodent and two human cell systems<sup>5-42</sup>. As plotted, the data constitute a potency index, extending from weakly mutagenic and less toxic compounds to highly mutagenic agents that are toxic at very low concentrations. The relative increase in cytotoxicity is accompanied by a proportional increase in mutagenicity, that is, the slope of the regression relationship is  $1.03 \pm 0.03$ . The observed correlation between cytotoxicity and mutagenicity suggests that a determination of the  $D_{37}$  dose of toxic agents can be used to estimate the maximum potential-induced mutation frequency. In particular, these data permit the hypothesis that no agents will be found whose location on this graph is significantly above the upper dotted line. Whereas mutagenicity and cytotoxicity separately range over six orders of magnitude, no agent can

**Fig. 2** The induced frequency per viable cell (MF) calculated for the  $D_{37}$  exposure dose of the physical and chemical mutagens listed in Table 1. The loci include *hprt* (AG<sup>r</sup>, TG<sup>r</sup>), *aprt* (AA<sup>r</sup>) and *tk* (BUdR<sup>r</sup>), as well as resistance to ouabain (OUA<sup>r</sup>) involving presumed lesions in the Na<sup>+</sup>-K<sup>+</sup>-ATPase enzyme (EC 3.6.1.3). The inner mark within the bars represents the geometric mean of data for all systems, with the range of reported values indicated by the ends of each bar. The arrows refer to the author's data for the Chinese hamster ovary multiple marker system<sup>7</sup>. According to the assumptions listed in Fig. 1, the lower limit for determining the MF at the  $D_{37}$  would be  $10^{-6}$ .

induce more than approximately one forward mutation at a given locus per 100 cells surviving at the D<sub>37</sub> dose. If this hypothesis is valid, this is a biological limit to mutagenic potency that is demonstrated by compounds whose cytotoxicity is due solely to mutational events.

On the other hand, we believe the absence of points below the lower dotted line to be artefactual, representing the bias of reported mutagenesis studies for compounds whose ratio of mutagenicity to cytotoxicity is relatively high. There are compounds which would graph somewhere in this lower range; for example, a few derivatives of heterocyclic nitrogen mustard frameshift mutagens<sup>14</sup>, a metabolite of a polycyclic hydrocarbon<sup>37</sup>, and an inhibitor of DNA synthesis<sup>43</sup> are highly toxic, but are apparently non-mutagenic in mammalian *in vitro* test systems. Also, certain chemicals yield multi-phasic cell survival curves that cast doubt on the validity of the D<sub>37</sub> concept for these mutagens. The shaded area in Fig. 1 reflects values below the detection limit for the systems studied. The cytotoxicity data for non-mutagens would also fall within this range. Thus, the dynamic range for forward mutations in mammalian *in vitro* systems is approximately four orders of magnitude (from the lowest detectable level to the highest possible mutagenic potency at the D<sub>37</sub> level of cytotoxicity). Compounds near the bottom of this range will presumably be of greater concern as cytotoxic agents than as mutagens.

The relative mutagenicity of different compounds at a given cytotoxicity (Fig. 1) is not significantly related to the class of mutagen or the forward mutation marker scored. This is shown in Fig. 2, which displays the observed values of the mutation frequency per locus at the D<sub>37</sub> dose for different classes of mutagens at different genetic loci. This variation is also not due to systematic differences among cell systems (data not shown).

Cytotoxicity, as defined (Fig. 1), may result from genetic (DNA-related) and non-genetic mechanisms of injury. Agents that induce the highest mutation frequencies at the D<sub>37</sub> dose may have the tightest coupling between genetic injury and lethality, that is, the cytotoxicity related to DNA damage pre-

dominates over other forms of general toxicity. Agents inducing lower mutation frequencies at the D<sub>37</sub> dose may produce a larger proportion of non-genetic injury.

The remarkable similarity among mutation frequencies at equitoxic concentrations has been noted by others for several mutagens<sup>5,6,17,37</sup>. The correlation between cytotoxicity and mutagenicity need not be due solely to the same type of cellular damage causing both lethal and mutational events<sup>4</sup>; factors that influence the effective exposure of the cells to chemical mutagens (toxification, detoxification) may affect both end points proportionally.

Additional data are needed to establish that partitioning of genetic and non-genetic toxicity induced by a mutagenic agent can be estimated from the magnitude of mutation induced at the D<sub>37</sub> dose. However, the data in Fig. 1 indicate that cytotoxicity as measured by the D<sub>37</sub> dosage provides a quantitative estimate of potential mutagenicity. Where appropriate, more specific bioassays can then be applied to determine precisely the *in vitro* mutagenic potency.

This work was performed under the auspices of the US Department of Energy by the Lawrence Livermore Laboratory under contract no. W-7405-ENG-48 and Interagency Agreements IAG-D5-E681-AN and AO with the Environmental Protection Agency.

## Hyperdiploid species hybrids for gene mapping in *Xenopus*

SPONTANEOUS endo-reduplication in the female germ line of hybrids has made it possible to produce several strains of isogenic *Xenopus*, providing one of the many features required of a laboratory animal<sup>1,2</sup>. The usefulness of *Xenopus* in the laboratory, however, would be improved if a gene map were available. We report here that hybrids can also be used to define linkage groups and their assignment to chromosomes. Our method is based on the possibility of creating aneuploid *Xenopus* which are diploid for the chromosomes of one species but have supernumerary chromosomes of a second species<sup>3</sup>. This method complements those already available<sup>4-8</sup>, and has the advantage that because traits can be monitored in the whole animal, a large repertoire of markers will be made available.

Figure 1 is a schematic presentation of how such animals are obtained, in this case for *X. laevis* × *X. gilli* hybrids. First generation hybrid females from this and other species combinations frequently produce diploid eggs from allotetraploid oocytes produced by endo-reduplication in the germ line. These oocytes have a complete set of bivalents from each parent species, synapsis being restricted to endo-reduplicated identical chromosomes<sup>1,9</sup>. Fertilised by sperm of one of the parent species, such eggs develop into triploid females (WZZ) because the female determinant W is dominant<sup>10</sup>. Triploid oocytes of such backcross females show a diploid number of bivalents, presumably the two homologous sets of chromosomes, with the third genome consisting of univalents. No trivalents have been observed<sup>9</sup>. The eggs thus contain a complete haploid chromosome set of the backcross species, *X. laevis* in our example, and, on the assumption of a random distribution of univalents, 0–18 chromosomes of the other species. Random distribution is indeed observed in the case of the easily recognisable nucleolus organiser chromosome. Fertilised again by *X. laevis* sperm, hyperdiploid embryos are obtained which are diploid for *X. laevis* but trisomic for a random selection of *X. gilli* chromosomes. Most of these zygotes undergo abnormal embryogenesis and die<sup>3</sup>, but 1–3% of them reach adulthood.

We have analysed 14 such hyperdiploid adults for karyotype and for the expression of *X. gilli*-specific characters. Antisera raised in *X. laevis* (as described elsewhere<sup>11</sup>) enabled us to detect by immunoelectrophoresis up to six *X. gilli*-specific serum antigens (Fig. 2), one of which was the heavy chain of low-molecular weight immunoglobulin (7S, IgG-like). Antiserum B10 was made specific for *X. gilli* Ig by immunoabsorption; A84 also contained antibodies against *X. gilli* Ig. We have not established the homologies between the serum proteins revealed by the different antisera. Two *X. gilli*-specific erythrocyte antigens were distinguished by lysis after iso-electrofocusing of specific antibodies (antisera A38 and A39).

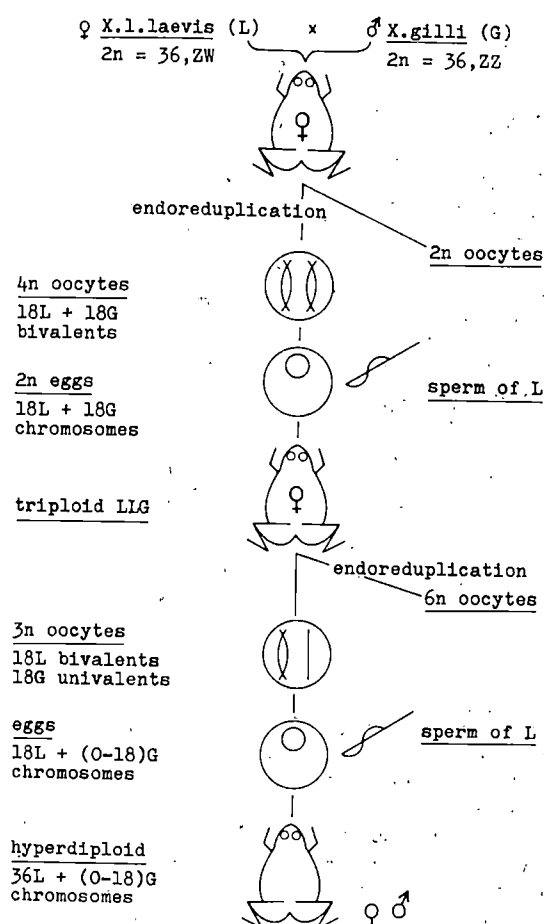

Fig. 1 Schematic presentation of pedigree of hyperdiploid *Xenopus* species hybrids.

Haemagglutination with antiserum A37 revealed an additional *X. gilli* erythrocyte antigen. Table 1 shows that *X. gilli* Ig and the erythrocyte surface antigens segregated as unlinked characters. They were not linked with either the single serum protein revealed by antiserum A85 or with those revealed by antiserum A82. This is in agreement with results obtained on diploid backcross animals of clone LG 15 (ref. 11) where, in contrast to most other LG clones, there was recombination between *X. gilli* and *X. laevis* chromosomes<sup>2</sup>. These characters depend therefore on genes on separate chromosomes. The lack of linkage between erythrocyte surface antigens suggests that some of them may represent minor histocompatibility antigens rather than major ones.

Chromosomes were prepared from phytohaemagglutinin-stimulated leukocyte cultures<sup>12</sup>. The karyotypes of both species are similar ( $2n = 36$ ) except for a chromosome pair with a

**Fig. 2** Immunoelectrophoretic analysis of the serum of eight hyperdiploid *Xenopus* hybrids with the antiserum A84. Serum samples in the wells from LL(G) animals nos. 4–13, and *X. laevis* (L) control. Antiserum A84 in the trough. Cathode to the left. Migration conditions: 1 h, pH 8.6, 5 mA per slide. Note the expression of only two *X. gilli* antigens, one of which is immunoglobulin (Ig, heavy chain) by animal no. 12, and 3 to 5 antigens by the other specimens. *X. laevis* control is negative. The karyotype of animal no. 5 shows groups (A–G) of similar chromosomes; supernumerary chromosomes on a second line.

secondary constriction specific for *X. gilli*<sup>13</sup>. The chromosomes can be classified into seven groups (Fig. 2) on the basis of relative length and arm ratio<sup>6</sup>, but individual chromosome recognition requires differential staining. Whereas the total number of supernumerary chromosomes can be determined (Table 1), their assignment to groups remains uncertain. Nevertheless, the nucleolus organiser chromosome (group F) is easily recognised in both mitotic and interphase cells and can be excluded as a carrier of one of the characters checked so far. Acrocentric chromosomes can also be counted. Animals 9, 13 and 14 had only two supernumerary acrocentric chromosomes; thus, not more than two of the characters analysed may depend on group G chromosomes. The four specimens which were not trisomic for the chromosome of group D were also deficient for one of the *X. gilli* erythrocyte antigens, indicating the possible chromosome location of the corresponding gene.

Some animals had a hypertriploid constitution due to failure of second meiotic division. Because the second meiotic division segregates chromatids, eggs which retain the second polar body contain a diploid set of *X. laevis* chromosomes as well as both chromatids of the *X. gilli* univalents distributed at meiosis I. Zygotes are, therefore, triploid for *X. laevis* and supernumerary for pairs of *X. gilli* chromosomes. Animal 12 had a bimodal chromosome number with 36 and 44 chromosomes. It is not certain whether the karyotype found in a given tissue is representative for the whole animal. Mosaicism could arise after non-disjunction during ontogenesis because the original zygotic constitution might be improved through the loss of supernumerary chromosomes.

It is striking that in spite of the variable degree of hyperdiploidy, most animals had most of the *X. gilli* characters studied. Was this attributable to redundancy of genes? Because several levels of ploidy occur in *Xenopus*<sup>14</sup>, one might consider both *X. laevis* and *X. gilli* to be ancient tetraploids. Even a restricted number of supernumerary chromosomes could then contain one of the originally duplicated genes. This would also imply that activity of duplicated genes has been conserved during evolution and that our methods do not distinguish between the various alleles. It seems more likely that survival of aneuploids is better when animals are functionally hypotriploid rather than trisomic for only a few chromosomes.

## 17 $\beta$ -Carboxamide steroids are a new class of glucocorticoid antagonists

GLUCOCORTICOID hormones exert many of their effects by modifying the activity of certain enzymes in target tissues, probably as a result of alterations in gene expression<sup>1</sup>. Experimental models have been developed in which enzyme induction by various steroids correlates well with their anti-inflammatory, thymolytic and glycopeptic properties. This is the case for tyrosine transaminase in cultured rat hepatoma (HTC) cells<sup>2,3</sup>. Studies in this system showed that, in addition to glucocorticoid agonists, partial agonists and antagonists could be identified<sup>4</sup>. The latter compete with agonists for binding to the intracellular glucocorticoid receptor but do not trigger the glucocorticoid effect<sup>5</sup>. Compounds which specifically antagonise glucocorticoid action at the target cell would be useful for the treatment of certain diseases characterised by excessive production of glucocorticoids<sup>1</sup> and for further studying the molecular mechanism of action of these hormones. However, unlike anti-androgens and anti-oestrogens<sup>6</sup>, the only known glucocorticoid antagonists are natural steroid hormones (such as progesterone and testosterone) or their analogues, which interact with their own receptors and plasma binding proteins and are therefore not very

**Fig. 1** Glucocorticoid receptor binding of 17 $\beta$ -carboxamide derivatives of dexamethasone. Livers from adrenalectomised male rats (Wistar, 250 g) were homogenised in buffer containing 20 mM Tris, 20 mM 2-mercaptoethanol, 3 mM MgCl<sub>2</sub> and 20% glycerol, pH 7.5. The homogenate was centrifuged at 105,000g for 2 h to yield the cytosol. Cytosol aliquots were incubated with [1,2,4(*n*)-<sup>3</sup>H]triamcinolone acetonide (28 Ci mmol<sup>-1</sup>, Radiochemical Centre). After 2 h at 0°C, specific binding to the glucocorticoid receptor was determined in duplicate by charcoal adsorption assay<sup>5</sup>. *a*, Inhibition of binding of 35 nM triamcinolone acetonide by increasing concentrations of dexamethasone and four of its derivatives (for nomenclature, see Table 1). specific. We report here that new derivatives of dexamethasone, a specific glucocorticoid agonist which does not bind to rat or human plasma transcortin<sup>5</sup>, can block the induction of tyrosine transaminase in HTC cells.

The novel steroids listed in Table 1 were synthesised and purified in our laboratory (P.F. and P.L., in preparation). They include the 17 $\beta$ -carboxylic steroids obtained by periodic oxidation of cortisol, corticosterone and dexamethasone, respectively, and seven 17 $\beta$ -carboxamide derivatives. The possible interaction of these steroids with the glucocorticoid receptor was studied in liver cytosol from adrenalectomised rats, using as specific ligands <sup>3</sup>H-labelled dexamethasone or triamcinolone acetonide, both synthetic agonists. Even at a 1,000-fold excess the 17 $\beta$ -carboxylic compounds DCAC, HCAC and DXO (see Table 1 for structures) barely inhibited binding of the <sup>3</sup>H-labelled steroids. However, after coupling the 17 $\beta$ -carboxyl group of DXO with various amines, clear inhibition by these dexamethasone derivatives was observed (Fig. 1*a*). The benzylamine-substituted compound DXB was the most active, a 10-fold excess being sufficient to produce a 50% reduction in the binding of the potent glucocorticoid, triamcinolone acetonide (Fig. 1*a*). This phenomenon was further investigated using different concentrations of radioactive ligand. Double-reciprocal plots suggested that the 17 $\beta$ -carboxamide derivatives

inhibited binding of triamcinolone acetonide to a homogeneous population of receptor sites in a competitive manner. Representative experiments are shown in Fig. 1*b*. The order of affinity was DXB > DXH > DMP > DXP > DXM > DXN > DCACP > DXO, with an equilibrium dissociation constant for DXB (0.8–1.1 × 10<sup>-7</sup> M) as high as that of corticosterone, the natural glucocorticoid in rats.

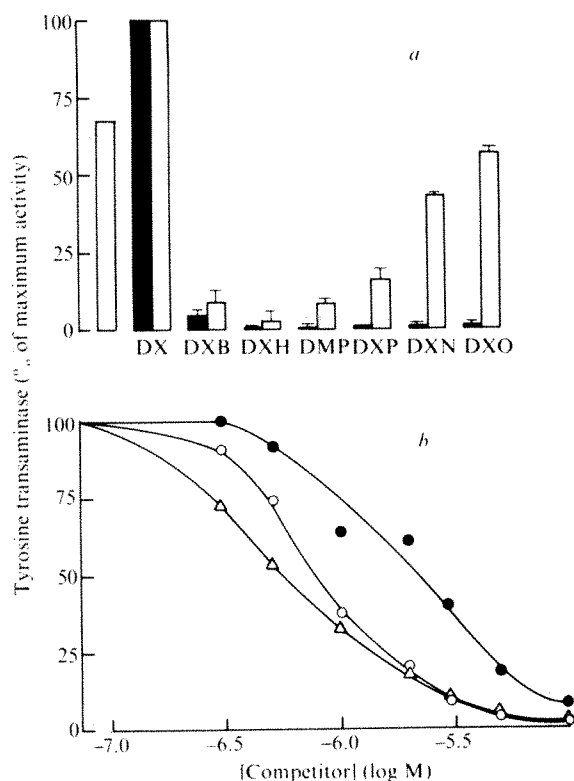

One might therefore predict that some of the dexamethasone derivatives would mimic the action of dexamethasone on tyrosine transaminase activity in HTC cells. Surprisingly, in conditions where dexamethasone produced a 10–15-fold increase of tyrosine transaminase activity, neither of the 17 $\beta$ -carboxamide steroids at concentrations up to 10 μM significantly modified the baseline activity of this enzyme (shaded bars in Fig. 2*a*). However, when assayed for receptor binding in HTC cell cytosol, the synthetic steroids competed with <sup>3</sup>H-labelled dexamethasone as they did in rat liver extracts. The order of affinity was the same. Tyrosine transaminase induction experiments were therefore carried out in which HTC cells were incubated with mixtures of dexamethasone and 17 $\beta$ -carboxamide steroids. We found that, although devoid of intrinsic glucocorticoid activity, DXH and DMP could inhibit the stimulating effect of dexamethasone on tyrosine transaminase by more than 85% (open bars, Fig. 2*a*). DXB was slightly less inhibitory than DXH because it had a very small agonist activity of its own. The other steroids also antagonised the glucocorticoid effect, in keeping with their affinity for the HTC receptor (Fig. 2*a*). The latter observation suggests that the inhibition of tyrosine transaminase is not a nonspecific action of high concentrations of the dexamethasone derivatives. Data in Fig. 2*b* support this interpretation, as it shows that the anti-glucocorticoid effect is dose dependent and that the order of potency of the inhibitors is consistent with their affinity for the HTC receptor.

Unlike natural corticosteroids, their 9 $\alpha$ -fluoro-derivatives do not bind to transcortin, the plasma corticosteroid-binding globulin. We examined whether this difference was maintained after carrying out the 17 $\beta$ -substitutions described here. Plasma

**Fig. 2** Anti-glucocorticoid activity of 17 $\beta$ -carboxamide derivatives of dexamethasone (DX). Rat hepatoma tissue culture (HTC) cells were resuspended in serum-free medium containing 0.1% (w/v) bovine serum albumin and incubated at 37 °C for 16 h in the absence of steroid or in the presence of 10  $\mu$ M dexamethasone to determine, as described previously<sup>4</sup>, the maximum tyrosine transaminase activity of the culture. The latter was 11.4–23.7 mU per mg protein, depending on the experiment, whereas it was 1.7–2.3 mU per mg protein in untreated cultures. Parallel cultures were also exposed to the other steroids, alone or in combination (for nomenclature, see Table 1). *a*, Shaded bars: cultures exposed to 10  $\mu$ M of a single steroid, as indicated. Open bars: cultures exposed to 25 nM dexamethasone alone (first bar on the left) or in combination with 10  $\mu$ M of the steroid indicated. Values given are the range obtained from two to four experiments. *b*, Effect of varying concentrations of the three most potent 17 $\beta$ -carboxamide derivatives on tyrosine transaminase activity in cultures exposed to 25 nM dexamethasone.  $\Delta$ , DXB;  $\circ$ , DXH;  $\bullet$ , DMP.

from adrenalectomised rats was incubated with <sup>3</sup>H-labelled corticosterone and binding to transcortin determined as described elsewhere<sup>5</sup>. We found that a 1,250-fold excess of HCAC, DCAC and DCACP inhibited corticosterone binding by 94, 77 and 71%, respectively, whereas the 9 $\alpha$ -fluoro-derivatives had either no effect or inhibited the binding by only 6–9% (DXB, DXN).

Our results show that glucocorticoid antagonists which bind to the receptor with high affinity can be derived from the synthetic agonists dexamethasone and desoximethasone. Some of the binding properties of these novel steroids are consistent with structure–activity relationships previously defined for the HTC cell glucocorticoid receptor<sup>7</sup>. First, the data confirm the importance of the steroid side chain in assigning both the potency (affinity for the receptor) and the activity class (agonist or antagonist). We now find that the loss of potency on removal of the carbon atom in position 21 can be partially restored by coupling various amines at this position. Crystallographic data (M. Devos, P.F. and P.L., unpublished) make it unlikely that the nitrogen atom could substitute for the oxygen atom of the 21-hydroxyl group as an acceptor in a putative hydrogen bond with the receptor. Rather, binding of the 17 $\beta$ -carboxamide

steroids would involve the hydrophobic interaction of the new side chain with the receptor site, as the affinity increases with increasing hydrophobicity of the amine. However, other substituents on the steroid skeleton retain their typical influence on the binding: DCACP and DXP have a potency ratio similar to that of the parent compounds cortisol and dexamethasone. Also, the fact that DMP has a greater affinity than DXP shows that the 17 $\alpha$ -hydroxyl group has the same unfavourable effect on the binding to the HTC receptor in 17 $\beta$ -carboxamide derivatives as in the pregnene series<sup>7</sup>. The persistence of this effect in the absence of a C-21 carbon atom suggests that it could result from a specific influence of the 17 $\alpha$ -hydroxyl group on the orientation of the C<sub>20</sub> ketone as suggested earlier<sup>8</sup>. Finally, our results show that conversion of an agonist into an antagonist is compatible with modifications (1–2 unsaturation; 9 $\alpha$ -fluor-, 16 $\alpha$ -methyl- and 11 $\beta$ -hydroxyl-substitutions) which promote high affinity for the receptor and/or prevent the steroid from binding to plasma transcortin and to cellular proteins other than the receptor. This has important implications for the development of more potent anti-glucocorticoids and receptor-specific ligands possessing chemically reactive functions which would be very useful for receptor purification by affinity chromatography.

## Guinea pig prostate is a rich source of nerve growth factor

NERVE GROWTH FACTOR (NGF) is essential for the development of sympathetic nerve cells<sup>1</sup>. The richest known source of NGF is the submaxillary gland of the adult male mouse<sup>2</sup>, and NGF from this source has been completely purified and thoroughly characterised<sup>3</sup>. The active entity ( $\beta$ -subunit) is a protein comprising a dimer of identical 118-residue chains<sup>4,5</sup>. Another form of mouse NGF, the 2.5S form, has been isolated<sup>6</sup> and shown to differ from the  $\beta$  entity in that some of the

monomeric chains have undergone enzymatic cleavage of the amino-terminal octapeptide and carboxy-terminal arginine residues<sup>3,4,7-9</sup>. The 2.5S dimer therefore contains both 118-residue chains and shortened chains. The salivary gland of the mouse seems to be unique in that the corresponding glands of the rat, guinea pig, cow, pig, rabbit and man contain no NGF<sup>10,11</sup>. No other clearly characterised source of NGF in mammalian tissue *in vivo* has been reported. We now report a new, rich source of NGF—the prostate glands of the adult male guinea pig.

NGF activity in soluble extracts of guinea pig prostate glands (dorsal and ventral lobes) was measured using a biological assay<sup>12-14</sup> in which the NGF content of a tissue is assessed by the ability of an extract to promote the outgrowth of nerve fibres from explants of dorsal root ganglia from 8-d chick embryos cultured for 24 h in specified conditions. The assay gives the NGF concentration in terms of a biological unit (BU), defined as the amount of NGF required to produce optimum fibre outgrowth. Assuming the same specific activity for guinea pig prostate and mouse submaxillary NGFs, the guinea pig gland is found to contain  $1.8 \pm 0.5$  mg NGF per g wet weight (mean  $\pm$  s.e.m., range 340–9,925  $\mu$ g,  $n = 22$ ). This organ therefore seems to be of similar potency to the mouse submaxillary gland. The levels in the latter organ (0.3 to 5 mg NGF per g wet weight) are known to vary according to the strain of mouse<sup>15</sup> and the extraction procedure.

Both whole antiserum and antibodies purified by affinity chromatography<sup>16</sup> against mouse submaxillary gland NGF were able to inhibit completely the biological activity of the prostate extracts in tissue culture (see ref. 17). The amounts of pure antibody required to block 1 BU ml<sup>-1</sup> *in vitro* of purified mouse NGF and crude extracts of prostate glands were not significantly different (0.62–1.25  $\mu$ g ml<sup>-1</sup> and 0.31–0.62  $\mu$ g ml<sup>-1</sup>).

Extracts of guinea pig prostate gland were tested by immunodiffusion against antiserum to purified mouse NGF (Fig. 1), and thereby compared with mouse NGF. The interaction of the precipitin lines shows that there are antibodies that recognise determinants common to both mouse and guinea pig NGFs, but that the mouse antigen has determinants not present in the guinea pig NGF (spur formation). This implies that a substantial proportion (note length and intensity of spurs) of the antibodies recognise mouse but not guinea pig NGF. The common antigenic sites may be related to the biologically effective site(s) of the proteins, the structure of which might be expected to be conserved, while the other part(s) of the molecule may be more variable between species.

The NGFs were also compared by immunoprecipitation with purified antibodies against mouse NGF, followed by SDS-gel electrophoresis (Fig. 2). Mouse submaxillary glands and guinea pig prostate glands were extracted in the presence of enzyme inhibitors (see Fig. 2 legend) to prevent the enzymatic cleavage of NGF in the crude extracts. In these conditions, most of the mouse NGF remains as the  $\beta$ -subunit (molecular weight of the monomer 13,259, refs 3–5), although a significant proportion exists in the 2.5S form in spite of the presence of enzyme inhibitors. (The SDS gel shows both the 118-residue monomers from the  $\beta$  and the 2.5S forms and the shorter monomers from the 2.5S NGF alone.) The greater intensity of the higher molecular weight band indicates that the  $\beta$  form predominates. In contrast, the guinea pig NGF shows a single band in the same position as that of the 118-residue monomer from mouse NGF. Omission of enzyme inhibitors during homogenisation gives rise to an increase in the proportion of the 2.5S form of mouse NGF while the guinea pig material remains as the  $\beta$ -subunit. Of several possible explanations, two obvious ones are either that the guinea pig factor is less susceptible to enzymatic cleavage or that the appropriate proteases are present at lower levels in the prostate gland.

The levels of NGF in the guinea pig prostate gland have also been estimated using a two-site radioimmunoassay based on purified antibodies against mouse NGF<sup>18</sup>. The radioimmunoassay and biological assay results were in reasonable agreement,

around 35% of the levels expected from the biological assay being detected. The major cause of the discrepancy seems to be the use of antibodies raised against mouse NGF, only some of which recognise guinea pig NGF (see immunodiffusion results), and the capacity of the radioimmunoassay system is thereby substantially reduced. Details of the use of the radioimmunoassay to measure NGF from species other than the mouse will be published elsewhere.

The observation that only a certain proportion of the antibodies to mouse NGF recognise guinea pig NGF contrasts with the similarity of the amount of antiserum required to block 1 BU of guinea pig NGF *in vitro* to the homologous titre. This could be due either to differences in the specific activities of the factors from the two sources or, possibly, to differences in the relationship between the antigenic sites and the sites associated with biological activity.

The significance of the presence in the accessory sex organs of agents with such potent effects on the sympathetic nervous system is not clear, but it is possible that the NGFs have a physiological role unconnected with, and in addition to, their effects on neuronal tissues. The levels of NGF in the mouse submaxillary gland show a well characterised developmental increase<sup>2</sup> and a marked sex difference<sup>19-21</sup>. A similar situation seems to apply in the reproductive system of the guinea pig. The high levels of NGF *in vivo* thus appear after the development of the sympathetic nervous system<sup>22,23</sup> and in the absence of any significant sexual dimorphism in the responsive neuronal tissues<sup>1,24,25</sup>. The actions of NGF on the sympathetic nervous system may require only low levels of the agents, which are attained (although not necessarily detected with the assays

**Fig. 1** Comparison of guinea pig and mouse NGFs by immunodiffusion. Wells 1,3,5: 20  $\mu$ l of an extract of guinea pig prostate gland, containing 240  $\mu$ g NGF per ml (by biological assay). The tissue extract was prepared in distilled water and the lyophilised material was further extracted in 50 mM ammonium acetate/acetic acid buffer pH 4.0, containing 1 mg ml<sup>-1</sup> bovine serum albumin, 200  $\mu$ g ml<sup>-1</sup> sodium azide, 50  $\mu$ g ml<sup>-1</sup> pancreatic trypsin inhibitor and 5 mM phenylmethanesulphonyl fluoride. The solution was centrifuged (22,000g, 30 min) to remove insoluble material, returned to pH 7.2 with NaOH, centrifuged again to clarify, and stored at  $-70^{\circ}\text{C}$ . This procedure removed many proteins from the crude extract but all the NGF was recovered, as judged by biological and radioimmunological assays. Wells 2,4,6: 20  $\mu$ l of a solution (in 50 mM Tris-HCl buffer pH 8.5) of purified mouse NGF<sup>18</sup>, at a concentration of 250  $\mu$ g NGF per ml. Well 7: 20  $\mu$ l of a solution (in 50 mM Tris-HCl buffer pH 8.5) of lyophilised sheep antiserum to mouse NGF<sup>18</sup> (60 mg ml<sup>-1</sup>). Immunodiffusion plates were made up of 0.4% agarose containing 0.1% Thimerosal. Plates were incubated at  $20^{\circ}\text{C}$  in a humidified atmosphere for 48 h, washed for 5 d in 150 mM NaCl solution to remove non-precipitated proteins, stained for 1–2 h in 0.25% Coomassie brilliant blue in 150 mM saline, destained for 3 d in 150 mM saline, and photographed. An identical result was obtained when wells 2, 4 and 6 contained an extract, prepared as described above, of mouse submaxillary gland, containing 160  $\mu$ g NGF per ml.

**Fig. 2** SDS-gel electrophoresis of immunoprecipitates of guinea pig and mouse NGFs. Two guinea pig prostate glands (7 ml) and two mouse submaxillary glands (5 ml) were homogenised with a Potter ground glass homogeniser in the volumes shown of 50 mM Tris-HCl buffer pH 7.4 containing 1% Triton X-100, 300  $\mu\text{g ml}^{-1}$  phenylmethanesulphonyl fluoride, and 20  $\mu\text{g ml}^{-1}$  pancreatic trypsin inhibitor. Homogenates were centrifuged at 22,000g (30 min) and stored at  $-50^\circ\text{C}$  until required; the supernatants were recentrifuged at 25,000g for 20 min after thawing and immediately before use. 100  $\mu\text{l}$  of guinea pig extract and 60  $\mu\text{l}$  mouse extract were incubated overnight at  $4^\circ\text{C}$  with 10  $\mu\text{l}$  Nonidet P40 detergent, 250 and 230  $\mu\text{l}$  respectively of a solution (in 50 mM Tris-HCl buffer pH 7.2, containing 150 mM NaCl) of purified sheep antibodies<sup>16</sup> to mouse 2.5S NGF (0.73 mg antibodies per ml) and Tris-NaCl buffer to a final volume of 400  $\mu\text{l}$ . Pilot experiments determined that these ratios of antigen to antibody were at the equivalence point. Immunoprecipitates were collected by centrifugation at 15,000g for 10 min and washed three times with 500  $\mu\text{l}$  Tris-NaCl buffer containing 2.5% (v/v) Nonidet P40. The immunoprecipitates were then dissolved in the sample buffer for electrophoresis (15% glycerol, 5% 2-mercaptoethanol, 2.25% SDS, 0.01% bromophenol blue and 0.0625 M Tris-HCl buffer pH 6.8) by heating at  $90^\circ\text{C}$  for 10 min. The solubilised immunoprecipitates were subjected to SDS-15% polyacrylamide gel electrophoresis according to the method of Laemmli<sup>29</sup>. The slab gel was performed in an apparatus similar to that described by Studier<sup>30</sup>. The slab gel was stained with 0.25% Coomassie brilliant blue in methanol acetic acid water (5:1:5 by volume) solution and destained in the same solution. (i), (ii), Top and bottom respectively of the SDS-polyacrylamide gel; (iii), bromophenol blue front. a, Immunoglobulin heavy chains; b, immunoglobulin light chains; c, position of the intact monomer of mouse  $\beta$  and 2.5S NGF, and of the guinea pig NGF; d, position of the smaller monomer from mouse 2.5S NGF. 1, Purified mouse NGF, 4  $\mu\text{g}$ . Both chains are entirely converted to the smaller chain, as found in 2.5S NGF, when NGF is purified according to ref. 18. 2, Mouse NGF immunoprecipitate. 3, Guinea pig NGF immunoprecipitate. 4, Purified mouse NGF 2  $\mu\text{g}$  (as above).

presently available) in developing (and female) animals. Another, possibly sex-linked, function is conceivable for these proteins, for which very high levels of NGF are required.

From a practical point of view, the high levels of NGF in the guinea pig prostate gland make this source an attractive alternative to the male mouse submaxillary glands. Interestingly, in view of the appearance of an epidermal growth factor (EGF) in the mouse submaxillary gland together with the NGF<sup>26-28</sup>, preliminary studies indicate that the guinea pig prostate gland could be a source of EGF of a potency comparable with or greater than the mouse submaxillary gland.

We thank Professor M. Schachter, Dr Barbara Banks, Dr F. L. Pearce and Professor H. Thoenen for valuable discussions. Financial assistance was given to G.P.H. by the SRC, the Wellcome Trust, and EMBO.

## Lipidic intramembranous particles

THE nature of intramembranous particles has recently been discussed in relation to the mode of freeze fracturing<sup>1,2</sup>. It has been argued that particles that do not show complementarity (complementary pits on the opposite fracture face) are a reflection of protein penetrating the membrane. The protein

**Fig. 1** An equimolar mixture of egg-lecithin, isolated according to established procedures, and cardiolipin (bovine heart cardiolipin) with a  $\text{Ca}^{2+}$ /cardiolipin molar ratio of 0:1 is dissolved in ether and injected according to the method described by Deamer and Bangham<sup>8</sup> in a buffer containing 150 mM NaCl and 25 mM Tris, pH 7.5. The purity of the lipids was found to be at least 99% as evidenced by TLC on silica-gel G using the elution system chloroform/methanol/acidic acid (93:30:12). Shadowing direction is indicated by arrows.  $\times 52,000$ .

giving rise to an intramembraneous particle is plastically deformed during the fracturing procedure and is probably pulled out to one of the two fracture faces. Moreover we have argued that particles showing complementarity (pits) are possibly of lipidic origin. This latter hypothesis was mainly based on the determination of the nature of the intramembraneous particles of the outer membrane of *Escherichia coli*. These complementary particles were shown to be determined by lipopolysaccharide<sup>3,4</sup>. We show here that lipid can by itself form intramembraneous particles showing complementarity and that these particles may be inverted micelles of phospholipid sandwiched between lipid monolayers.

To test the hypothesis that lipid can give rise to intramembraneous particles with complementary impressions on the opposite fracture face, we have studied primarily lipids that can exist in non-bilayer phases. Good candidates are phosphatidylethanolamines from natural sources<sup>5</sup> and especially cardiolipin in the presence of  $\text{Ca}^{2+}$  (ref. 6) which can form the hexagonal phase II.

Recently we have shown that the transition of cardiolipin from the bilayer configuration to the hexagonal phase by addition of  $\text{Ca}^{2+}$  occurs by an intermediate phase of particles about 70 Å in diameter, as visualised by freeze fracturing<sup>7</sup>. This intermediate phase is characterised by the <sup>31</sup>P NMR spectrum

which indicates isotropic motional averaging. This phase, which exists at  $\text{Ca}^{2+}$ -cardiolipin ratios below 0.6, can be interpreted as inverted micelles, that is particles with hydrophilic cores and hydrophobic edges.

To see whether such inverted micelles can form intramembraneous particles we have prepared model membranes of an equimolar mixture of lecithin and cardiolipin at a low  $\text{Ca}^{2+}$  cardiolipin ratio as described in Fig. 1 legend.

Freeze fracturing shows fracture faces of bilayers organised predominantly in large unilamellar structures. Also some multilamellar structures are found. On the fracture faces of these bilayers particles of a rather uniform size are present. The mean diameter is 100 Å (s.d. 14 Å;  $N = 100$ ). The pits are about 30 Å smaller. Fracture faces bearing exclusively particles or exclusively pits are found (Fig. 1a) but also fracture faces with both particles and pits can be observed (Fig. 1b). If  $\text{Ca}^{2+}$  is removed by EGTA extraction, neither particles nor pits are observed—only smooth fracture faces. On the other hand excess  $\text{Ca}^{2+}$  results in a homogeneous conglomerate of globules about 100 Å in diameter. (These latter results will be published in detail elsewhere.)

The most important conclusion that can be drawn from these observations is that lipid by itself can form intramembraneous particles and that such particles show complementarity. These particles might arise from invaginations of the bilayer, but this is unlikely as one should expect a variation in the size of particles and consequently in the size of the pits, which is not the case. In our opinion these particles represent inverted micelles of phospholipid sandwiched between lipid monolayers.

## The role of spectrin in erythrocyte membrane-stimulated actin polymerisation

PROTEINS on the cytoplasmic surface of the erythrocyte membrane, including spectrin and actin, are postulated to comprise the red cell cytoskeleton<sup>1–3</sup>, but little is known about the role of actin or its association with the membrane. We have reported that monomeric (G) actin added to erythrocyte ghosts selectively associates with a component at the cytoplasmic surface of the membrane<sup>4,5</sup>. We now show that this component is unlikely to be spectrin and that actin binding occurs by stimulated actin polymerisation.

Large amounts of added G-actin bind to the cytoplasmic surface of unsealed ghosts, but little or none binds to sealed ghosts or spectrin-actin-depleted inside-out vesicles<sup>4,5</sup>. After spectrin-actin-depleted inside-out vesicles (referred to here

**Fig. 1** Actin binding to vesicles reconstituted by preincubation with spectrin. Unsealed, spectrin-actin-depleted inside-out vesicles were prepared from ghosts<sup>18</sup> of freshly drawn human erythrocytes by one wash in ice-cold 0.3 mM sodium phosphate buffer, pH 7.6, incubation for 40 min in 40 volumes of 0.3 mM sodium phosphate buffer at 37 °C and two washes in ice-cold 0.3 mM sodium phosphate buffer. Crude spectrin (primarily spectrin, actin and band 4.1) was prepared by extracting ghosts in 0.3 mM sodium phosphate buffer, 37 °C and phosphorylated by incubating 1 mg spectrin in 1 ml of 100 mM NaCl, 10 mM Tris pH 7.4, 5 mM MgCl<sub>2</sub>, 50 μM ATP containing 1 μCi of <sup>32</sup>P-ATP and 200 μg erythrocyte kinase<sup>19</sup> at 37 °C for 30 min. Saturation of <sup>32</sup>P incorporation occurred after ~20 min. (33 mol PO<sub>4</sub> per mol spectrin in this experiment.) After phosphorylation, the <sup>32</sup>P-spectrin was purified on a sucrose density gradient<sup>6</sup> (similar results were obtained using spectrin which was phosphorylated after gradient purification). Vesicles (0.3 mg protein per ml) were incubated for 1 h on ice with the indicated concentrations of spectrin in 20 mM KCl, 2 mM MgCl<sub>2</sub>, 5 mM sodium phosphate pH 7.6, and 0.75 mM β-mercaptoethanol, washed once and resuspended in this same medium to a protein concentration of 0.25 mg ml<sup>-1</sup>. Control experiments confirmed that the amounts of crude, pure or phosphorylated pure spectrin which bound to vesicles were comparable when they were added at the same concentration (~60 μg per mg vesicle protein and 90 μg per mg for added spectrin concentrations of 10 and 40 μg ml<sup>-1</sup> respectively). Preparation of [<sup>3</sup>H]G-actin from rabbit skeletal muscle and quantification of <sup>3</sup>H-actin binding as described previously<sup>5</sup>. Briefly, 40 μg ml<sup>-1</sup> [<sup>3</sup>H]G-actin was incubated in a volume of 0.8 ml with 0.25 mg ml<sup>-1</sup> membrane protein in 20 mM KCl, 5 mM sodium phosphate pH 6.5, 2 mM MgCl<sub>2</sub>, 1 mM ATP and 0.75 mM β-mercaptoethanol (actin-binding buffer) on ice for 1 h. Samples were layered on 0.2 ml of 20% w/v sucrose (made in actin-binding buffer) in 0.5 ml polyethylene microfuge tubes, centrifuged at 18,000 r.p.m. for 25 min in a Sorvall SS34 rotor and the tips, containing the membrane pellet, frozen in liquid N<sub>2</sub>, cut off, placed in 10 ml of scintillation fluid and counted for <sup>3</sup>H. No <sup>3</sup>H-actin sedimented through the sucrose in the absence of membranes in any of the conditions studied.

simply as vesicles) were reconstituted with crude spectrin (primarily spectrin, actin and band 4.1; for nomenclature see ref. 1), their ability to bind added G-actin became nearly equal to that of unsealed ghosts<sup>5</sup>. As the major component of crude spectrin is spectrin itself, we tested the ability of the purified protein to stimulate actin binding (Fig. 1). Crude spectrin was effective at stimulating actin binding to inside-out vesicles at low concentrations, but purified spectrin had little or no effect, even when added in concentrations sufficient to saturate the spectrin binding capacity (ref. 6, and our unpublished data) of the vesicles.

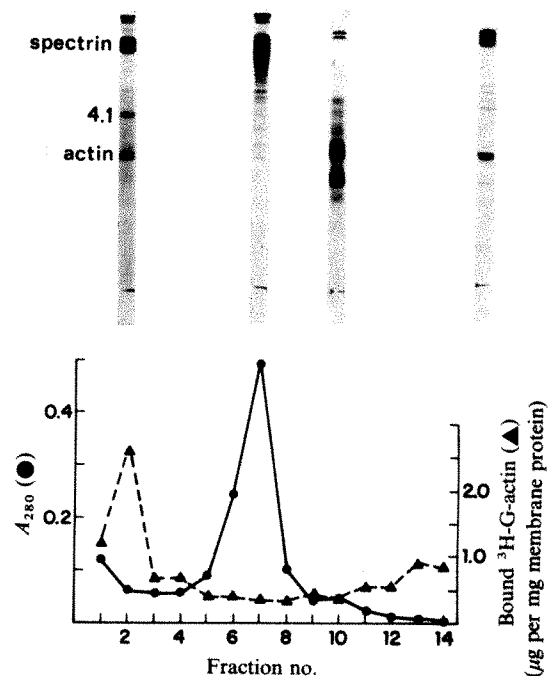

As the interaction of spectrin and actin has been reported to be sensitive to spectrin's state of phosphorylation<sup>7</sup>, we considered the possibility that the purified spectrin was inactive because it had become dephosphorylated. However, reconstitution of vesicles with phosphorylated spectrin did not stimulate actin binding (Fig. 1).

The ability of crude, but not purified spectrin to stimulate actin binding prompted us to explore the possibility that some component of crude spectrin other than spectrin itself was responsible for this effect. Crude spectrin was centrifuged on a 12-ml linear 5–20% sucrose gradient which was fractionated into 14 aliquots. Samples of vesicles were reconstituted with each of the gradient fractions and tested for their ability to bind added G-actin (Fig. 2). The only fraction capable of stimulating binding was found near the bottom of the gradient and contained spectrin, red-cell actin, and band 4.1. The ability of this fraction to stimulate binding was less than an equivalent amount of crude spectrin, indicating some loss of stimulatory activity during purification.

These results show that some component of crude spectrin other than spectrin itself, can stimulate actin binding to red-cell membranes. We propose that this stimulated binding occurs as a direct result of induced polymerisation of the added G-actin because: (1) actin binding depends on the presence of Mg. (2) Actin binding is non-saturable. (3) Actin binding can be prevented by DNase I and cytochalasin B<sup>5</sup>. (4) Actin binding is accompanied by terminal phosphate hydrolysis from the tightly bound ATP of the actin molecule<sup>8</sup>, a hallmark of actin polymer formation. In addition, we have shown that vesicles reconstituted with crude spectrin and subsequently incubated with G-actin become covered with actin filaments which emanate from their surface<sup>5</sup>. Decoration of these filaments with heavy meromyosin (Fig. 3) reveals that they all have the same polarity, arrow heads pointing towards the membrane, indicating that although polymerisation is nucleated by the membrane, growth proceeds at the free, distal end of the filament<sup>9</sup>. Thus, the polarity of the filaments is opposite to that seen *in situ* in other cell types<sup>10–13</sup>.

In line with our conclusion that crude spectrin stimulates actin binding to vesicles by polymerisation<sup>8,14</sup>, we have used a novel microassay for actin polymerisation<sup>8,14</sup> and found that crude spectrin can stimulate actin polymerisation in solution, whereas purified spectrin, whether phosphorylated or not, does not stimulate actin polymerisation. This suggests that there is a direct relationship between polymerisation-inducing capacity and stimulation of actin binding to membranes.

Our attempt to define the components of crude spectrin responsible for stimulating actin binding requires further exploration, as the gradient fraction capable of stimulating binding contains all three of the major components of crude spectrin (spectrin, red-cell actin and band 4.1). Their presence near the bottom of the gradient suggests that they may be associated in a supramolecular complex migrating with a sedimentation coefficient considerably greater than any of the pro-

**Fig. 2** Stimulatory effect of spectrin gradient fractions on actin binding by vesicles. Crude spectrin was centrifuged on a 5–20% sucrose gradient as described in Fig. 1. The gradient was fractionated, and 200-μl aliquots of each fraction were incubated in 1 ml of 20 mM KCl, 2 mM MgCl<sub>2</sub>, 5 mM sodium phosphate pH 7.6, 0.75 mM β-mercaptoethanol containing spectrin-actin-depleted inside-out vesicles (0.3 mg protein) for 1 h at 4 °C. Samples of vesicles reconstituted with each of the gradient fractions were washed once and resuspended in this same buffer to 0.25 mg protein per ml and tested for actin binding as described in Fig. 1. The absorbance of each gradient fraction (solid line) and actin bound by vesicles reconstituted with that fraction (dashed line) are plotted. 5% SDS polyacrylamide gels<sup>20</sup> of selected gradient fractions are shown above the corresponding fraction numbers, the gel to the far right being the crude spectrin.

**Fig. 3** Electron micrograph of negatively stained inside-out vesicles reconstituted with crude spectrin, incubated with G-actin and subsequently decorated with heavy meromyosin. Spectrin-actin-depleted inside-out vesicles were reconstituted with crude spectrin ( $40 \mu\text{g ml}^{-1}$ ) and incubated with  $40 \mu\text{g ml}^{-1}$  G-actin as described in Fig. 1. After incubation for 20 min with the actin, the vesicles were sedimented through 20% w/v sucrose to separate them from unbound actin and applied to a formvar-coated grid. The grids were rinsed three times with 0.6 M KCl, 10 mM Tris pH 7.6 followed by application of  $0.2 \text{ mg ml}^{-1}$  heavy meromyosin in the same medium. Grids were stained with 1% uranyl acetate.  $\times 230,000$ .

teins separately, but each of these proteins may be capable of forming multimeric associations with itself (spectrin is known to form tetramers and actin to form filaments). One or both of these factors may contribute to the formation of the active complex, but the presence of actin in the complex is of special significance because small quantities of purified F-actin, when reconstituted onto vesicles by the method used for crude spectrin or the gradient fractions, can stimulate the subsequent binding of added G-actin. Moreover, when purified F-actin is added to G-actin in solution at actin concentrations and solvent conditions identical to those used in our binding studies, rapid and extensive actin polymerisation takes place (data not shown). These findings suggest that crude spectrin and the active gradient fraction may contain F-actin, or actin aggregates, which are responsible for the polymerisation-related binding of added G-actin. This conclusion can be reconciled with the fact that unmodified red-cell ghosts and crude spectrin do not contain structures identifiable as F-actin by proposing that the actin on the membrane, and as extracted in crude spectrin, exists in small aggregates or proto-filaments consisting of three to five monomers. Such F-actin aggregates may be highly efficient in promoting filament formation in the presence of an excess of G-actin<sup>15</sup>, both in solution and when bound to red-cell membranes, and would allow red-cell actin to be bound and distributed in a homogeneous and apparently amorphous manner over the membrane surface.

Our hypothesis of membrane-bound actin aggregates can explain the membrane-induced actin polymerisation observed with ghosts and reconstituted inside-out vesicles, as well as crude spectrin-induced actin polymerisation in solution. Our

observation that purified spectrin has none of these activities, however, contradicts the results of Pinder *et al.*<sup>7</sup>, who measured viscosity changes and concluded that phosphorylated spectrin can induce actin polymerisation in solution. To reconcile our observations with those of Pinder *et al.*, we suggest that their spectrin, which was chromatographed on Sephadex G-200, contained red-cell actin aggregates which induced the polymerisation of added G-actin. Observations by other workers<sup>16,17</sup> provide clear evidence that spectrin prepared from the void volume fractions of this or other large-pore gels will be contaminated by small quantities of actin and other proteins. The effect of spectrin phosphorylation on actin viscosity might be to induce the cross-linking of adjacent filaments which had already been formed.

This research was supported by grants NIH HL 17411 and NSF PCM 77-13962. We thank C. Korsgren and P. Jackson for technical assistance.

## Comparison of the predicted model of $\alpha$ -lytic protease with the X-ray structure

THERE are several methods for the prediction of secondary structural features of protein molecules from the amino acid sequence<sup>1-5</sup>. Application of these methods to proteins of unknown tertiary structure has met with mixed results<sup>6,7</sup>, and it has been suggested that it is the protein structural type which will determine which predictive method will succeed<sup>8</sup>. There is also great interest in the *ab initio* prediction of tertiary structures of proteins<sup>9-11</sup>, but this has not yet been achieved. One possible method for predicting the tertiary structure of an enzyme is by the use of a known amino acid sequence and a previously determined tertiary structure of another related homologous isofunctional enzyme. This method was used by McLachlan and Shotton<sup>12</sup> in an attempt to fit the  $\alpha$ -lytic protease sequence into the polypeptide chain folding of elastase<sup>13</sup> and chymotrypsin<sup>14</sup>. It has also been used to predict the tertiary structure of tropo-nin C (ref. 15). Now that the structure of  $\alpha$ -lytic protease is known<sup>16</sup> to a resolution of 2.8 Å, we can assess the accuracy of

**Fig. 1** *a*, A stereo drawing of the  $\alpha$ -carbon atom backbone of  $\alpha$ -lytic protease, with each  $\alpha$ -carbon atom position numbered according to that of chymotrypsinogen A as described in detail in ref. 20. The active site region is located in the central portion of this drawing, where  $\alpha$ -carbon atom positions of the catalytic quartet of Ser 214, Asp 102, His 57 and Ser 192 are evident. The three disulphide bridges 42–58, 137–159 and 191–220 present in this molecule are denoted by dashed virtual bonds. *b*, The  $\alpha$ -carbon atom drawing of  $\alpha$ -lytic protease (solid virtual bonds) is superimposed on that of elastase (open virtual bonds) in a manner designed to maximise topological equivalences<sup>24</sup>. Every fifth  $\alpha$ -carbon atom position of each enzyme is numbered; additional numbering is also present for residues discussed in the text. See Fig. 1 of ref. 12 for more details of the model proposed.

such predictions. The tertiary structures of two related bacterial serine proteases, SGPA and SGPB and their structural relationship to the pancreatic enzymes have been published previously<sup>17–19</sup>. Many of the conclusions drawn from those studies are also applicable to the present discussion on  $\alpha$ -lytic protease and need not be repeated. Rather, we shall consider the basic premise of sequence homology in phylogenetically distant proteins being used to deduce tertiary structures. A recent realignment<sup>20</sup> of the amino acid sequences of Gly-Asp-Ser-Gly-Gly proteases, which was based on the known topological equivalences of  $\alpha$ -carbon atoms, indicates an overall sequence identity of only 18% between  $\alpha$ -lytic protease and elastase. We show here that this low value is independent of the environment of the topologically equivalent polypeptide chains (whether the residues are internal or external) and that the sequence identity is associated with only those residues which are in the immediate vicinity of the active site quartet, Asp 102, His 57, Ser 195 and Ser 214.

The complete amino acid sequence determination of this bacterial serine protease from *Myxobacter* 495 revealed short stretches of sequence which were highly homologous to presumably corresponding regions in the sequences of the mammalian pancreatic enzymes—chymotrypsin, trypsin and elastase. This homology and the similar catalytic behaviour towards peptide substrates<sup>22</sup> suggested that  $\alpha$ -lytic protease might have a tertiary structure similar to that of the mammalian enzymes despite the fact that it has a much smaller molecular

weight than porcine elastase (19,900 compared to 25,900). In regions of the polypeptide chain of  $\alpha$ -lytic protease which do not contain residues of the active site, the sequence homology with the pancreatic enzymes is so low that serious sequence misalignments have resulted<sup>12,21</sup> and persisted even with the knowledge of the tertiary structure of SGPB<sup>17</sup>. In spite of the lack of sequence homology, there is considerable tertiary structural equivalence which is far more extensive and presumably more conserved than the amino acid sequence identities would suggest.

The polypeptide chain folding of  $\alpha$ -lytic protease (represented by  $\alpha$ -carbon atom positions only) is illustrated in Fig. 1*a*. Figure 1*b* shows the  $\alpha$ -carbon atoms of  $\alpha$ -lytic protease superimposed on the  $\alpha$ -carbon atom backbone drawing of elastase<sup>23</sup> (coordinates for elastase are from the Brookhaven Protein Data Bank). The superimposition of these two enzyme structures was achieved using a computer program written by W. Bennett of Yale University and is based on the methods described by Rossmann and Argos<sup>24</sup>. Examination of Fig. 1*b* shows that there is indeed topological equivalence of  $\alpha$ -carbon atoms between  $\alpha$ -lytic protease and elastase. However, this tertiary structural homology<sup>20</sup> (55% of the  $\alpha$ -carbon atoms of  $\alpha$ -lytic protease (108 residues) have a topologically equivalent  $\alpha$ -carbon atom in elastase within an r.m.s. deviation of 2.08 Å) is limited to the central core, and in particular to those stretches of polypeptide chain which support or contain residues directly involved with substrate binding or the catalytic event.

An alternative representation of the topological equivalence between  $\alpha$ -lytic protease and elastase is given in Table 1 which summarises those 76 residues in both domains of these enzymes (domain I, residues 16–120; domain II, 121–245) which have the highest degree of topological equivalence. It is clear from Table 1 that the number of topologically equivalent residues in domain II is more than double that in domain I. This is also true if the topological comparisons are done treating each domain independently. There are only three strands of polypeptide chain which superimpose well in domain I and these strands support the two catalytically important residues His 57 and Asp 102. The apparently high level of amino acid identity (36%) is the result of the small absolute number of topologically equivalent residues (22) in domain I.

Domain II has 54 topologically equivalent  $\alpha$ -carbon atoms in six strands of antiparallel  $\beta$ -pleated sheet. The degree of sequence identity between  $\alpha$ -lytic protease and elastase is relatively low (22%). There is only one strand (that supporting Ser 195) which has extensive sequence identity, as shown in Table 1. The lack of sequence homology between the first three topo-

logically equivalent strands of domain II is not sufficient to predict a correct model successfully. Indeed, there is only one residue that is structurally required out of the 25 residues comprising these three strands. Gly 140 is structurally invariant<sup>20</sup> and is required as such; any side chain at this position would sterically interfere with the side chain of Asp 194, a residue essential to determining the proper catalytically active conformation of serine protease binding sites<sup>25,26</sup>. The three strands of topologically equivalent residues in domain I of  $\alpha$ -lytic protease were correctly predicted from the elastase fold<sup>12</sup> as were strands 4 and 6 domain II. However, the remaining four strands, although topologically equivalent in the two enzymes, had so little sequence homology that the correct register was not discerned. Clearly, what is conserved throughout the evolution of these important digestive molecules is the three-dimensional structure and not the amino acid sequence, except in the immediate vicinity of the catalytic quartet.

The  $\alpha$ -lytic protease and pancreatic elastase have a similar substrate specificity<sup>22,27</sup>. The steric interactions whereby these two structurally related enzymes achieve this specificity for small

Those residues enclosed in boxes are chemically identical in  $\alpha$ -lytic protease and elastase. The amino acid sequences are expressed in the 1 letter code<sup>30</sup> and have been taken from ref. 20.  $\Delta$  is the r.m.s. deviation of the  $\alpha$ -carbon positions after optimisation and is expressed in Å units. The average r.m.s. deviation for domain I is 0.96 Å; for domain II, 1.12 Å. Those residues which are buried (internal) have a line drawn over the residue number. The strands are drawn diagrammatically to represent the antiparallel  $\beta$  hydrogen bonding seen in Fig. 1.

**Fig. 2** Stereo drawing of the active site of  $\alpha$ -lytic protease. The polypeptide main chain bonding is shown with solid black bonds. All oxygen atoms present are distinguished by solid black circles. Hydrogen bonds involving active site residues are illustrated as dashed lines. The side chains of Met 192, Met 213 and Val 217A occlude the primary binding pocket. The conformational lability of Arg 192B would not contribute to such a blockage of the substrate binding site.

side chains (Ala, Val, Ser) are quite different and were not predicted from model building<sup>12</sup>. The active site and substrate binding region of  $\alpha$ -lytic protease is shown in Fig. 2. The primary specificity site of the pancreatic-like serine enzymes involves the residues from 191–195 and 214–220. Elastase achieves its specificity because of the presence of Val 216 and Thr 226 (ref. 13), both side chains of which block the entrance to a hydrophobic cavity that exists in  $\alpha$ -chymotrypsin<sup>4</sup>; the topologically equivalent residues in  $\alpha$ -chymotrypsin are Gly 216 and Gly 226 (ref. 20). Residue 216 is also a glycine in  $\alpha$ -lytic protease and therefore the structural reason for its specificity must differ from that of elastase and from that proposed<sup>12</sup>.

Two important insertions in the sequence of  $\alpha$ -lytic protease as compared with that of elastase occur in the active site region<sup>20</sup>. The first of these insertions is a dipeptide at position 192. As a consequence, the side chain of Met 192 occludes the specificity pocket of  $\alpha$ -lytic protease, whereas the side chain of Gln 192 in elastase is directed away from this binding pocket. The second insertion is a pentapeptide at position 217. The side chain of Val 217A of this insertion is also directed into the specificity pocket (see Fig. 2). Consequently, the primary binding site of  $\alpha$ -lytic protease has room for substrate residues with side chains only as large as that of a valine residue<sup>16</sup>. In the region of residues 214–220, McLachlan and Shotton had misaligned (by four residues) the sequence of  $\alpha$ -lytic protease with that of elastase and had placed a glutamine residue at position 216 and concluded that this residue in  $\alpha$ -lytic protease would diminish the size of the primary specificity site, as does Val 216 in elastase. However, this glutamine residue is really residue 217B in the sequence and is located on the surface of the enzyme with its side chain pointing away from the active site (Fig. 2). Moreover, that misalignment had placed an asparagine residue at position 214 whereas a topologically equivalent serine residue has been found at this site in all of the serine protease structures that have been reported to date<sup>16–19,23,26,28</sup> (including the evolutionarily unrelated subtilisin<sup>29</sup>).

The extensive degree of structural similarity of these two serine proteases, in spite of the lack of sequence identity of topologically equivalent residues, makes it necessary to evaluate the expectations of a structural prediction. Our comparison of the 2.8-Å structure of  $\alpha$ -lytic protease with the 2.5-Å structure of elastase shows that the molecules are very similar in the regions near those residues important for catalysis. However, it does not seem possible to rely on primary structural homology (or lack thereof) to predict correctly and accurately an unknown structure from that of an isofunctional protein molecule of known tertiary structure. Resort to secondary structure predicting rules<sup>1–5</sup> would not necessarily offer much help, for in the stretch 131–138 of  $\alpha$ -lytic protease an  $\alpha$ -helical conformation is

incorrectly predicted whereas the corresponding region of elastase is indifferent to either  $\alpha$  or  $\beta$  structure<sup>1</sup>. If the results of protein structure prediction are to be used only to detect the possibility of conformational similarity and thus evolutionary homology, then such techniques can be useful<sup>12,15</sup>. However, if the interest is in the structural detail of substrate binding sites, or, in the conformation of the catalytically important residues, then the present methods of predicting structure are not satisfactory.

# matters arising

## Human activity and the erosion of soils on chalk

IN their letter<sup>1</sup> relating to beech bark disease and lynchets, Lonsdale *et al.* refer to the probability of an acid non-calcareous soil overlying the chalk on their site. This type of soil seems to be very widespread in the west Sussex-east Hampshire region, more so than the chalky soil which is generally supposed to be the characteristic one, and is by no means always underlain by Pleistocene or earlier deposits. In fact, on shallow slopes, a highly calcareous soil seems to occur only where human disturbance has facilitated erosion; this usually means in ploughed fields or on the negative aspects of lynchets such as Lonsdale *et al.* have observed. Steep slopes, including the chalk scarp, are, on the other hand, often calcareous. The wood in which Lonsdale *et al.* are working does indeed seem to contain the non-calcareous soil, although not in its most acid form; samples taken from it<sup>2</sup> in 1970, outside the lynchet area, were mostly found on analysis to have a non-calcareous, non-iron, mineral content of ~70%. They are significantly less calcareous than samples from the neighbouring ploughed fields, and this difference has been found in several such areas of old woodland cover and arable, even though the two resemble each other in topographic and other respects.

## Aerosol anomalies preceding earthquakes

IN his article on aerosol anomalies preceding earthquakes Tributsch<sup>1</sup> suggests that there is emission of positive ions

before an earthquake occurs and that these ions are responsible for the many reports of animal disturbance before the major event itself. We have been investigating electrical phenomena associated with stress and failure in rocks and ceramics and some of our data may be applicable to Tributsch's hypothesis.

For testing, we normally attach connections to the rock via conductive epoxy or hammered-in phonograph needles. These points are connected to one or more electrometers before the specimen is placed in compression or bending. As the load is applied we see a series of pulsed currents that we associate with piezoelectric effects. As the load is increased there is a steady state current of the order of  $10^{-10}$  A that we associate with the stress induced migration of ions<sup>2</sup> or the inception of a continuous series of internal microfractures. In any case the current pattern and areas of highest current can be used to predict areas of high residual stress and the location of ultimate failure.

As the specimen approaches failure we observe the emission of both electrons and positive ions with energies up to 15 eV at current levels of  $10^{-11}$  A. If the experiment is done in a darkened room there are flashes of light as the material begins to fail. These flashes are not observed in a helium environment but are intensified in a water vapour or pure oxygen environment; we suggest that the electrons and ions are exciting water or oxygen molecules that decay by photon emission. This electron and ion emission may well be responsible for the effects discussed by Tributsch as well as the earthquake light phenomena reported by Derr<sup>3</sup>.

A full report on this work will be given at the Fourth International Congress on Rock Mechanics in September at Montreux.

## Historical climatology

WE should like to join Professor H. H. Lamb in clarifying a point in our article on historical climatology<sup>1</sup>. We stated that the correlation between Lamb's English winter severity index values for the decades between AD 1100 and 1400 and Alexandre's decadal indices for winters in Belgium was very low. We attributed this largely to the fact that Alexandre used thoroughly criticised and carefully evaluated historical data, whereas the sources available to Lamb when he pioneered the method were compilations of variable but generally poor quality.

It is necessary to add that in using the indices to reconstruct temperatures, Lamb himself expressly avoided undue emphasis on the decadal values as such, instead relying on half-century mean values derived from them<sup>2</sup>. These smoothed values correlate much better with Alexandre's series. It is important to emphasise Professor Lamb's caution in this respect. Indeed, it was because his caveat evidently required reiteration that we originally chose to highlight the problems inherent in the decadal values.

## The impossibility of comminuting small particles by compression

KENDALL<sup>1</sup> has given a simple explanation of the impossibility of comminuting and crushing a brittle body by cracking when its size is smaller than a certain critical value. This size effect was demonstrated by applying the classical Griffith<sup>2</sup>

energy criterion to a brittle body of idealised geometry. However, it has been shown recently<sup>3</sup> that the Kendall theory could be improved, and brought into complete agreement with the Griffith theory, if allowance were made for the restraint to the free lateral movement inevitably experienced by the brittle body during compression. Assuming the lateral restraining force to be a small fraction,  $\alpha$ , of the axial compression,  $F$ , and following exactly Kendall's<sup>1</sup> procedure and notation, the cracking force is

$$F = \frac{1}{(1 - w/d + 8\alpha c/d)} \left( \frac{2ERd}{3} \right)^{1/2} \quad (1)$$

where  $c$  is the crack length.

The force at the transition from cracking of the brittle body to its gross yielding under the platen is given by the solution to the quadratic

$$\frac{1}{Yd} \left( \frac{F}{b} \right)^2 - \frac{F}{b} (1 + 8\alpha c/d) + \left( \frac{2ERd}{3} \right)^{1/2} = 0 \quad (2)$$

In particular, if the particle size is reduced to a critical value

$$d_{crit} = \frac{32ER}{3Y^2(1 + 8\alpha c/d)^4} \quad (3)$$

cracking becomes impossible. Equations (1)–(3) differ from their counterparts in Kendall's paper by the presence of the very crucial term  $8\alpha c/d$ .

Based on my experimental data<sup>3</sup> and that of Kendall<sup>4</sup>, I have argued that the restraining force would be very small especially if the size of the body is reduced. In fact, a value of  $\alpha$  between 1/100 and 1/200 seemed most appropriate.

For the model material (polystyrene) tested by Kendall<sup>1</sup> the  $c/d$  ratio in equation (3) for all samples was 1.25. Equation (3) suggests that for  $\alpha = 1/200$  the transition from brittle to ductile behaviour of polystyrene could be expected at a size of 3.69 mm as opposed to 4.48 mm predicted by Kendall's theory. The experimentally observed value was 3.6 mm (ref. 1). Expression (3) clearly is in better agreement with experimental data. Likewise, equation (3) predicts a crushing limit of around 0.85  $\mu$ m for calcium carbonate which is also in close agreement with the average particle size of 0.8  $\mu$ m to which calcium carbonate is reduced after prolonged milling.<sup>1</sup>

## Agonist regulation of $\alpha$ -adrenergic receptor numbers

THERE have recently been several reports which indicate that agonist-induced desensitisation of cells might be explained, at least in part, by reductions in the number of receptors exposed at the surface of target cells; the evidence has been particularly clear for  $\beta$ -adrenergic receptors. Thus, it is not surprising that studies have been designed to see whether agonist-induced desensitisation of cells to  $\alpha$ -adrenergic stimulation might be explained in a similar way. Two reports have now described fairly rapid agonist-induced decreases in  $\alpha$ -receptor number<sup>1,2</sup>, and another described a modest rise in  $\alpha$ -receptor number in animals treated for several weeks with reserpine to induce supersensitivity<sup>3</sup>.

In their report, Cooper *et al.*<sup>2</sup> seemed to consider that the observed reduction in receptor number provided an adequate explanation for the desensitising effects of agonists; no other mechanisms were apparently considered. However, this position is untenable, as their main observation was that a 50% decrease in receptor number in adrenaline-treated platelets (assessed by dihydroergocryptine binding) was accompanied by an essentially complete loss of two cellular responses to the same agonist (aggregation and 5-hydroxytryptamine secretion).

Surely, this must mean that only a small proportion of the desensitising effect of agonist treatment can have been mediated through the change in receptor number? Most of this desensitising effect was presumably a result of some event which was brought about by receptor activation but which did not involve any changes in the number of exposed receptors. This is hardly surprising, as there is much evidence which indicates that in other tissues, especially smooth muscles, changes in receptor numbers are not likely to be the main mechanism whereby increased or decreased exposure to agonists brings about changes in cell sensitivity to those ligands which act at  $Ca^{2+}$ -mobilising receptors<sup>4–6</sup> (of which the  $\alpha$ -adrenergic receptor is one type<sup>7</sup>). These alternative mechanisms for changes in sensitivity may not be as conceptually simple nor as well understood as the changes in receptor number, but they cannot be ignored when the available data are incompatible with an explanation based solely on changes in receptor number.

ALEXANDER AND HANDIN REPLY—Michell is correct, of course, in stating that agonist-induced desensitisation of physiological responses might not be explainable on the basis of a 40–50% decrease in receptor number, as determined by ligand binding with <sup>3</sup>H-dihydroergocryptine (DHEC), an  $\alpha$ -adrenergic antagonist. It was not our intention to imply that this was the sole explanation for adrenaline-induced desensitisation in the platelet. However, we do not agree "that only a small proportion of the desensitising effect of agonist treatment can have been mediated through the change in receptor number". Since submission of our paper, there has been a report on the desensitisation of  $\beta$ -adrenergic receptors showing that the percentage of receptors identified by agonist binding is decreased to an extent considerably greater than the 35% decrease in receptor number determined by antagonist binding. These data suggest that agonists and antagonists bind different forms of the  $\beta$ -adrenergic receptor<sup>1</sup>. It has been reported that  $\alpha$ -adrenergic agonists and antagonists bind to distinct states of the  $\alpha$ -adrenergic receptor and that <sup>3</sup>H-DHEC may label both the agonist and antagonist state<sup>2–5</sup>. If most of the decrease in <sup>3</sup>H-DHEC binding in platelets preincubated with (–)-adrenaline represents changes in the putative agonist state, then the observed decrease in receptor number may be sufficient to explain most of the  $\alpha$ -adrenergic agonist-induced desensitisation in platelets. This possibility requires further investigation using both agonist and antagonist binding assays.

The references on denervation supersensitivity may not be relevant to our work on desensitisation. In fact, it has recently been reported that  $\alpha$ -adrenergic receptors in rat cerebral cortex increase after chronic reserpine treatment, suggesting that an increase in receptor number may contribute to post-junctional supersensitivity<sup>6</sup>.

## Concepts of colour

J. D. Mollon

*Color Vision: An Historical Introduction.* By G. S. Wasserman. Pp. 224. (Wiley: New York and Chichester, UK, 1978.) £13.40.

THOSE who study colour vision are very aware of the history of their field. There are two reasons for this. First, the topic is one that has recommended itself to the strongest intellects: Newton, Thomas Young, Maxwell and Helmholtz have left writings that set models of experimental elegance and theoretical clarity for the modern researcher. Second, the advancement of the field has depended on an instructive sequence of conceptual insights, which must be recapitulated by each fresh student. It is therefore very appropriate that Professor Wasserman should adopt an historical organisation in his intermediate-level textbook on colour vision.

As actual history, Wasserman's account is patchy and largely limited to expositions of the main printed sources. His summary of the relevant parts of Newton's *Opticks* is accurate and very clear; but his treatment of other early material is unashamedly based on secondary sources and he entirely omits mention of the trichromatists of the first half of the eighteenth century. His account of the contribution of Maxwell and Helmholtz is excellent, but then he spoils himself by recommending that the three-receptor theory of colour vision, which is widely referred to as the Young-Helmholtz theory (and which is almost certainly correct), should instead be eponymously linked with Newton and Maxwell. That Maxwell should enjoy more credit is fair; but to associate the theory with Newton is to confound the whole history of the field. The most fundamental fact about colour vision is that of trichromacy, the fact that only three variables are needed in a colour-matching experiment; and it is sometimes said that trichromacy is implicit in Newton's colour circle and centre-of-gravity rule. But (as Wasserman himself very clearly explains) by mixing three primary colours that lie

on the circumference of Newton's circle, one can reach only that part of colour space enclosed by a triangle inscribed within the circle. Newton lacked the concept of imaginary primaries lying outside the colour circle; and he lacked that concept because he lacked in turn the idea of narrowly tuned transducers, supposing only that "... the Rays of Light in falling upon the bottom of the Eye excite vibrations in the *Tunica Retina*" (Qu. 12) and that these vibrations are "propagated through the solid, pellucid and uniform Capillamenta of the optic nerves into the place of sensation" (Qu. 23). The "several sorts of Rays" merely "make Vibrations of several bignesses, which according to their bigness excite Sensations of several Colours" (Qu. 13). As Newton understood neither the fact of trichromacy nor the trichromatic theory that was later introduced to explain it, I urge colleagues not to adopt Wasserman's suggestion that we should speak of the Newton-Maxwell theory.

The topics covered by Wasserman include colorimetry, colour blindness, component and opponent theories, zone theories, photometry, physiology. There are detailed discussions of the theories of Hurvich and Jameson and of Guth; of Land's experiments on colour contrast; of heterochromatic photometry; and of the early microspectrophotometric records. Wasserman has taken great pains to elucidate conceptual difficulties for students and this trouble is repaid by a very lucid text. I very much liked his discussion of imaginary primaries and his account of non-additivities of heterochromatic lights. There is a very helpful passage relating Granit's early reports of retinal 'dominators' and 'modulators' to the later electrophysiology.

But the book has two weaknesses. First, the coverage is unbalanced (the British come off especially badly). Rushton's reflection densitometry is dismissed as valueless in a sentence. Stiles' increment-threshold method passes entirely unmentioned, although the spectral sensitivities so derived are

close to linear transformations of the colour-matching functions and (from this evidence and from microspectrophotometry) now seem likely to represent the sensitivities of the cones themselves. (Indeed, although the book is illustrated with a great number of spectral sensitivities, amazingly there is nowhere shown a set that resembles the ones likely to be correct.) Nothing is said of one of the most interesting developments of the last decade, Zeki's demonstration of areas in the prestriate cortex that seem to be specialised for the analysis of colour.

Second, Wasserman has some heresies of his own to press upon the unsuspecting student. Thus the chapter on colour blindness is quite out-of-date and misleading and the author perpetuates one of the most notorious conceptual errors of the field, that of supposing that anomalous trichromacy can be explained by giving abnormal weightings to the signals from the three cones of normal vision. There is a lot of dubious talk about two-peaked photo-pigment sensitivities in invertebrates and in vertebrates, without any mention to the student that invertebrate pigments may be bistable (the two states corresponding superficially to a rhodopsin and a metarhodopsin) or that the evidence for visually significant short-wave peaks in vertebrate pigments is very slight. The recent microspectrophotometric measurements of goldfish receptors shown on p189 do indeed exhibit secondary *cis*-peaks, but the goldfish pigments are based on vitamin A<sub>2</sub> and Wasserman does not point out that the *cis*-peak of the long-wave human pigment (P565) would lie well below 400 nm, at wavelengths completely absorbed by the lens of the eye.

In summary, Wasserman's book is good in parts. Should this Curate's Egg be given to students? Only if accompanied by many, well placed pinches of salt. □

J. D. Mollon is Lecturer in Experimental Psychology at the University of Cambridge, UK.

## Biological properties of immunoglobulins

*Comprehensive Immunology*. Volume 5: Immunoglobulins. Edited by R. A. Good and G. W. Litman. Pp. 381. (Plenum Medical: New York and London, 1978.) \$18.58.

THIS is a multi-authored book containing 16 different articles. The style of each is governed more by the authors themselves than by any unifying editorial criterion. The length of the chapters is also very variable and bears no relationship to their general importance. Whether this is by chance or design, it turns out to be fortunate because, in general, the most extensively, and to my mind the better, reviewed subjects have also suffered the least from the unavoidable delay in publication of books of this nature.

The major emphasis is on the more classical immunochemistry problems concerned with the nature of the antibody-antigen interaction. Crystallographic, physicochemical, kinetic and thermodynamic data bring us a comprehensive picture of the general properties of the antibody-combining sites and, more importantly, of the outstanding and unresolved aspects of the problem. For those of us trying to understand the peculiarities of monoclonal antibodies in serological reactions, some of the chapters (particularly that by Karush on "The Affinity of Antibody: Range, Variability, and the Role of Multivalence") are very relevant. Yes, Cathou was right in saying, "Immunochemistry does not appear to be in any danger of an early death" (p76).

The first six chapters, which also include discussions on the structural basis of the effector functions of antibodies and other biological properties, take up well over half of the book. The other portion doesn't attempt a comprehensive coverage of other aspects of immunoglobulins, but a quick glance at the table of contents may give a misleading impression of the real subject matter. For instance, the short discussion by Ohno on the significance of gene duplication in Ig evolution is intended for the initiated and not to give a picture of the complexities of the contraction and expansion processes in the evolution of immunoglobulin gene pools. On the other hand, I found a considerable amount of information on subjects that are seldom reviewed: for example, on immunoglobulin-like molecules and possible functional ancestors of antibodies in lower species (chapter 8) and on the relative expression of  $V_H$  subgroups in

normal and abnormal immunoglobulins in man (chapter 13).

Chapter 10 reviews the structure of atypical immunoglobulins and their implications in terms of genetic control mechanisms. It is a great pity that Frangione did not have an extra year to write this chapter, as his pioneering ideas about a separate 'gene' for the hinge region could have crystallised with the discoveries of 'gaps' in the DNA structure. The book closes with a crisp "Overview on membrane immunoglobulins": the outstanding problems, the relevant facts and the prevailing opinions at the time of publication. Pernis has obviously made a great effort to try to include last-minute references and, in the rush, Berget *et al.* (1977) did not make it to the reference list.

A number of errors have crept into

the book here and there, some of which seem worthy of mention. For instance, Wang (chapter 9) refers to Huang as "Huong", and in chapter 10 section 4.1, called "Internal Deletions", the word "deleted" at the end of the first sentence is missing (deleted?).

According to the flap of my copy, the book was intended to "prvide" (*sic*) a foundation for the subsequent interpretation of the biological properties of immunoglobulins. It is difficult to say if it does *that*, but I think it is a serious contribution to the increasingly effective communication between experts talking such different languages.

César Milstein is Head of the Protein Chemistry Subdivision, Medical Research Council Laboratory of Molecular Biology, Cambridge, UK.

## Field theory

*Relativistic Quantum Fields*. By C. Nash. Pp.223. (Academic: London, New York and San Francisco, 1978.) £15; \$31.

IN the past five years we have witnessed an astonishing renaissance of field theory in elementary particle physics. On the one hand the Weinberg-Salam unified theory of weak and electromagnetic interactions has had considerable success in fitting a large variety of neutrino neutral current data; on the other hand quantum chromodynamics (QCD) predicted and explains the scaling violations observed in deep inelastic neutrino scattering. As a result it is now the conventional wisdom that these theories, or something quite like them, will eventually permit a full understanding of all of the fundamental interactions seen in nature, except perhaps gravity.

Such an understanding is still a long way off and it will come, if at all, only when our facility in using and thinking within the field theoretic formalism has advanced considerably beyond the present level. (I am thinking, for example, of the problem of quark confinement—plainly a non-perturbative effect which will need considerable technical progress to elucidate.) It is therefore a pleasure to welcome an excellent book by Charles Nash which develops some of the fundamentals of field theory with enough detail to teach the serious student how to undertake his or her own calculations. Most of the book is devoted to the  $\lambda\phi^4$  theory and quantum electrodynamics (QED), rather

than the non-abelian gauge theories (Weinberg-Salam and QCD) which launched the revolution. This is all to the good, as it permits the assimilation of unfamiliar techniques without the encumbrances of the new theories.

The first *sine qua non* of the new order is functional differentiation and integration, which is illustrated by the usual Gaussian integral. (Is this the *only* functional integral anyone has done?) Nash takes us gently through this, and even consoles us should we feel "a little perplexed or confused". "This is quite normal". Functionals on a Grassmann algebra are also considered. Next there is an extensive coverage of dimensional regularisation, a covariant and gauge invariant method for handling the infinite quantities which inevitably arise when evaluating radiative corrections in these theories. This is used to verify the Ward Identity and to compute the renormalisation constants in QED. The final chapter touches on the asymptotically free gauge theories, the Callan-Symanzik equation, and so on. However, the coverage is less full than that of the earlier material, and there is no treatment of spontaneous symmetry breaking in non-abelian theories. If these attractive theories do withstand further rigorous experimental tests, it is to be hoped that the author will be moved to write a companion volume dealing with these topics in the same detail. In the meantime the present book will certainly provide a lastingly useful and relatively painless introduction into a highly technical field.

D. Bailin is Lecturer in Theoretical Physics at the University of Sussex, Brighton, UK.

# Oxford Books for Students

## Physical Chemistry

**P. W. Atkins**

'It is a book of its time not only in content and outlook but in format and style too . . . could well become a milestone in the development of text books of physical chemistry.' *Chemistry in Britain*. 'An important and original work.' *Education in Chemistry*. 'The author is to be congratulated on the production of such a good text and the publishers for its presentation at a price within the reach of students.' *British Book News*. £17.50 paper covers £7.95

## Solutions Manual for Physical Chemistry

**P. W. Atkins**

This manual contains the author's detailed solutions of almost every one of the 1,060 problems contained in his textbook *Physical Chemistry*. It will be invaluable both to the instructors and lecturers who have adopted the parent text and to the students who use it themselves. Illustrated paper covers £4.50

## Primary Metabolism

**A Mechanistic Approach**

**J. Staunton**

The traditional line of demarcation between biochemistry and chemistry has dissolved in recent years as chemists and biochemists have joined forces in investigating the mechanisms of reactions which take place in living systems. This book introduces this area of common interest to students of both chemistry and biochemistry. The later chapters take account of the biological dimension by tracing representative metabolic pathways step by step to show how the constituent reactions mesh together to form a coherent metabolic machine. £6.50 *Oxford Chemistry Series*

## Secondary Metabolism

**J. Mann**

'It is encouraging to see published a book such as Dr Mann's, which is designed for the undergraduate and beginning researcher. His book is very well put together and should facilitate and encourage the preparation of undergraduate courses on modern natural products chemistry.' *Chemistry in Britain*. £9.75 *Oxford Chemistry Series*

## Thermodynamics and Statistical Mechanics

**P. T. Landsberg**

The basic ideas and mathematical formulations of thermodynamics are presented here in a concise and modern way. Topics covered include: negative temperatures; negative heat capacities; special and general relativistic effects; black hole thermodynamics; gravitational collapse; energy conversion problems; and efficiencies including simple heat pump theory. £8.50

## The Solid State

An Introduction to the Physics of Crystals for Students of Physics, Materials Science, and Engineering

**H. M. Rosenberg**

The topics covered include basic crystal structure, diffraction of waves, dislocations, specific heat, phonons, thermal and electrical conductivity, the physics of p-n semiconductor junctions, and magnetic and dielectric properties. For the second edition a chapter on superconductivity has been added. £5.50 paper covers £2.95 *Oxford Physics Series*

## Physical and Engineering Science for Technicians, Level I

**R. J. Besanko and T. H. Jenkins**

This new version of *General Engineering Science* is designed to cover the units in physical science and engineering science at Level 1 for students taking TEC Certificate and Diploma Programmes. Some additional material is included to satisfy college-devised units, and the book is also suitable for other courses at this level. Paper covers £2.95

## Scientific Models and Man

The Herbert Spencer Lectures, 1976

**Edited by Henry Harris**

In these lectures a group of distinguished men from different disciplines describe how current work in their own subject is changing their view of the world. Scientific models have been enormously influential in transforming the way in which we look at ourselves and at the universe: this book gives some indication of the way the world is going to look tomorrow. £3.25

# Oxford University Press

# Wiley

NEW YORK · CHICHESTER  
BRISBANE · TORONTO

## Advances in Enzymology and Related Areas of Molecular Biology Vol. 48

edited by **A. Meister**, *Cornell University Medical College*.

The forty-eighth volume in a continuing series of outstanding reviews by authorities in enzymology and related fields. The series reviews progress made in the various branches of this expanding science and has become essential to all who wish to keep abreast of the literature. (*Advances in Enzymology Series*)

April 1979 462 pages  
0471 04428 8 \$36.50/£19.50

## Basic Molecular Biology

by **F.W. Price**, *State University College, Buffalo, New York*.

This provides a thorough yet clear exposition of fundamental principles and concepts, describing both structure and function of molecules and how they interact with cell structures and organelles. It emphasises the primary importance and ubiquity of proteins in biological systems, relating each type of molecular complex to a functional theme.

April 1979 520 pages  
0471 69729 X \$22.50/£11.95

## Mechanisms of Cell Change

edited by **J.D. Ebert**, *Marine Biological Laboratory, Woods Hole, Massachusetts*  
and **T. Okada**, *Kyoto University, Japan*.

An authoritative, timely, and concise volume focusing on the central problem of development, based on the essential mechanisms underlying the development of integrated multicellularity, diversified tissues, and organismic wholeness. It includes detailed coverage of recent Japanese discoveries, since Japan has emerged as one of the world's centres of research in the field. The book is based on the proceedings of the 8th International Congress of the International Society of Developmental Biologists.

April 1979 358 pages  
0471 03097 X \$46.00/£24.00

## Contrasts in Behavior

edited by **E.S. Reese** and **F.J. Lighter**,  
both of the *University of Hawaii*.

An examination of the similarities and differences between various aquatic and terrestrial animal behavioural systems. This provides a wealth of background and reference material that offers fresh insights into both the methodology and some principles of animal behaviour. Parental care, Lekking behaviour, sexuality, lateral display, communication, thermoregulation, aggregation, feeding, social behaviour, agnostic behaviour, social structure, and spacing, are all covered with comparison of diverse systems in new ways (such as spacing systems between fish and birds and behavioural thermoregulation between lake fishes and desert reptiles). Classical references are also examined.

April 1979 420 pages  
0471 71390 2 \$36.50/£19.50

## Methods of Biochemical Analysis Vol. 25

edited by **D. Glick**, *Stanford Research Institute, Menlo Park, California*.

Volume 25 of this ongoing series which deals with a particular determination or group of related determinants that are of great interest and use to biochemists. It includes chemical, physical, and biological assays, as well as basic techniques and instrumentation for the determination of enzymes, vitamins, hormones, lipids, carbohydrates, proteins, minerals, anti-metabolites. (*Methods of Biochemical Analysis Series*)

April 1979 392 pages  
0471 04397 4 \$38.95/£20.00

## Elements of General and Biological Chemistry 5th Ed.

by **J.R. Holm**, *Augsburg College, Minnesota*.

Focusing on chemistry as the molecular basis of life, this provides the necessary background for further studies and professional work in nursing and other allied health sciences, nutrition, physical education, and life sciences. It gives a broad view of biochemistry, covering carbohydrates, lipids, proteins, and enzymes, as well as the chemistry of respiration and clinically associated problems, and the chemistry of diabetes and of heredity. The book closes with a chapter on radiation and health and a study of radioimmunoassay. New emphasis is given to acid-base balance, blood gases, and the chemistry of respiration.

April 1979 608 pages  
0471 02224 1 \$19.50/£10.70

## Aspects of Biophysics

by **W. Hughes**, *Bowdoin College, Maine*.

Intended for those who have a basic knowledge of physics, chemistry and biology and who wish to see how more of the elementary parts of physics may be applied to the study of living matter. The author introduces representative topics from biophysics with references for discussions and focuses on general results, methods, and analyses.

April 1979 376 pages  
0471 01990 9 \$21.80/£11.95

## Schizophrenia: An International Follow-Up Study World Health Organization, Geneva.

This volume reports on the two-year follow-up of patients included in the International Pilot Study of Schizophrenia, a pioneering transcultural collaborative study of one of the most frequent, disabling and distressing mental disorders. The findings from nine countries reported here indicate important differences between the prognosis of schizophrenia in developing and developed countries, as well as the relation of these differences to psychosocial factors.

April 1979 456 pages  
0471 99623 8 \$34.00/£16.00

Baffins Lane · Chichester · Sussex PO19 1UD · England

## Amino acid analysis

*Amino Acid Determination: Methods and Techniques.* Second edition. Edited by S. Blackburn. Pp. 367. (Marcell Dekker: New York and Basel, 1978.) Swiss Fr. 82.

THIS will be a most useful book which should find its way on to the shelves of every amino acid analyst. Old hands will find new and valuable information, and beginners will find a thorough introduction to the field. Perhaps its best features are the extensive and thorough bibliography which accompanies each chapter and the author index, covering over 1,000 authors. Nevertheless, and despite its subtitle, this is *not* a laboratory manual in the sense of providing recipes and precise details of procedural matters.

There are 13 chapters of which the editor has written a short introduction and recent history (chapter 1), an equally short tailpiece (chapter 13) and three other chapters. Of the remaining eight chapters, five are by George W. Robinson and the others by experts in their particular areas.

Chapter 2 (by Blackburn) describes the preparation and hydrolysis of samples before analysis and is a useful survey of the methods and pitfalls in this necessary preliminary. There follow four chapters (3–6) by Robinson on the standard ion-exchange methods used in modern automatic analysis, dealing with the theory, development, and practical aspects such as resins, buffers and detection systems. Chapter 7, entitled "Automatic Analysers", is the least satisfactory in the book. Admittedly, information on makes of instruments and their capabilities and defects is necessarily ephemeral material but it is nevertheless very valuable information for anyone undertaking the purchase of a new analyser. This chapter could therefore have said much more about the strengths and weaknesses of the different instruments and their makers. For example, although the editor mentions the Rank-Hilger Chromospek in chapter 1 as possessing some "novel features", neither the instrument nor its features are mentioned in chapter 7. In fact, novel though they may be, there are serious disadvantages that could well have been discussed and compared with the pros

and cons of other makers' instruments.

Blackburn's chapter 8 on "Gas Chromatography" will be found useful by GC buffs no doubt, but for a method which, in the words of the Editor in chapter 1, "has failed to displace the amino acid analyser" this chapter is extraordinarily long (78 pages compared to a total of only 69 in chapters 3–7 on the analyser). This may be necessary to do the method justice, as it does have specialist uses; but the balance seems wrong.

The use of computers in amino acid analysis is well covered in chapter 9, and chapter 10 is a rag-bag of miscellaneous procedures and applications containing a useful section on dansyl amino acids. An unexpected blessing, at least for those with medical interests, is chapter 11 on "Physiological Fluids". This is a real mine of densely packed information. Finally, chapter 12 is a useful account of the relatively new techniques using pyridoxal derivatives of amino acids.

W. Ferdinand

W. Ferdinand is Senior Lecturer in Biochemistry at the University of Sheffield, UK.

## Viking missions

*To the Red Planet.* By Eric Burgess. (Columbia University Press: New York, 1978.) \$24.95.

ALTHOUGH all the plates and other illustrations in this book are in black and white, this is more than compensated for by the actual choice of graphic material and the informed, balanced and stimulating text. The opening chapters give a lucid account of the historical background and current state of knowledge regarding the planet Mars, the biophysical and biochemical bases of life as we know it, and how these topics relate to the objectives of the Viking missions.

Passages devoted to spacecraft instrumentation and hardware, which appear mainly in chapter 4, are treated in the contexts of the scientific rationale and mission planning. The emphasis here, as throughout the book, is sufficiently human in orientation that one does not lose sight of the involvement, the thoughts and reactions, of the project scientists; and the author pays due regard to maintaining the requisite attention to scientific and technical detail.

Burgess arranges his facts well and combines them with lively narrative and wit, not born of offhandedness nor

any trace of cynicism, but of the humour flexed by an author who really is in control of his material and who obviously feels a pressing need to communicate this to a wide spectrum of readers.

Each point of discussion is given a fresh paragraph, assisting the overall clarity, but a few sub-headings would not have gone amiss, particularly where the Viking lander experiments are described in chapter 7 and where conclusions are drawn in the final chapter. But this is not a serious detraction. Possibly through modesty the author may not have regarded his work as a book of reference. In view of the selection of topics and pictures discussed, and the high standard of his own exposition, it certainly could be regarded as such.

Burgess has undertaken a difficult task and performed it well; readers of the book will undoubtedly be rewarded. If they happen to be members of the public at large or specialists in planetary science, it will go a long way towards broadening their appreciation of the considerable amount of interdisciplinary thought, effort and coordination which has contributed to the success of the Mars Viking missions.

## Ageing of higher organisms

*Principles of Mammalian Ageing.* Second edition. By R. R. Kohn. Pp. 240. (Prentice-Hall: Englewood Cliffs, New Jersey, and Hemel Hempstead, UK, 1978.) \$19; £13.85.

GERONTOLOGY was born in optimism. It threatens to founder in verbiage. Papers and books are now appearing in quantity, while declining in quality, drowning the few really important studies in this field. Robert Kohn's book was there at the beginning of the boom, and it stands aside from the information explosion. Despite certain problems, this new edition restores to us a compact, well-written and refreshingly intelligent introductory text on the ageing of higher organisms.

The book begins by exploring the progressive crystallisation and toughening of inorganic materials as an analogy to illustrate ageing. It is an analogy which some may find weak and misleading, for ageing is manifest by increasing disorder rather than order. Nevertheless it serves the author's purpose, for he moves on to an excellent summary of the ageing phenomena in the extracellular materials of the body. The following sections deal with ageing within cells, briefly covering the evidence for age-related changes in the dynamic renewal of cellular constituents and for long-term biochemical deterioration. This is followed by a carefully ordered chapter on ageing of cell populations, which classifies cells according to their degree of continuing cell division within tissues. The rest of the book is concerned with the ageing of animals and here the author makes a good job out of the onerous task of summarising a highly complex and contradictory field.

The problem with the book is the author's penchant for selecting two or three seemingly contradictory papers as representative of major fields of ageing research, which then allows him to conclude that this work is inconclusive. For example, there is excellent evidence that dividing cell populations such as mammary gland cells, antibody-producing cells or haematopoietic cells show some age changes during the lifespan of the individual and will eventually cease division, although they are capable of outliving the organism from which they are derived. The author fails to mention significant work in this field and uses sparse studies to support a 'no-evidence' conclusion. He does the same with the exciting new field of the analysis of errors in macromolecules of senescent cells, with work on histones, on the question of protein

turnover, repair capacity, DNA synthesis and the genetics of ageing as a whole. A more penetrating analysis would have shown him that work which at first reading seems contradictory is in fact complementary, and would have enabled him to pick out the key papers in each field. This would have allowed him to draw constructive conclusions in each area, thus enriching the book.

The author's unwillingness to make conclusions derives in part from a certain failure to properly grasp molecular, genetic and evolutionary concepts as a whole. He remakes the classic *faux pas* that ageing exists because "old, non-reproductive animals compete with younger animals for food", which is the same as saying that ageing exists because of ageing. Besides this, scientists usually have some inner vision which guides their work, especially in such a complex and

exploratory field as ageing research. To some, ageing is a process of headlong over-differentiation. To others it is an ineluctable entropic deterioration of biological information. Krohn seems to see ageing as a kind of crystallisation or fossilisation of biological materials. Each man to his own. But it is important to be able to understand other researchers' ways of looking at the problem.

Yet it is easy to criticise a scientific text on the basis of selectivity. These criticisms do not alter the fact that the book holds together very well. Now that the number of papers on ageing is somewhere at the five figure level, a coherent and thoughtful introductory text such as this is no mean feat.

## Transfer RNAs

*Transfer RNA.* Edited by S. Altman. Pp. 356. (MIT Press: Cambridge, Massachusetts, and London, 1979.) \$30; £21.

THE concept of tRNAs as the essential links between nucleic acid and protein, has for over twenty years been a central theme of molecular biology in general and studies on protein biosynthesis in particular. It is now some thirteen years since the 'state of the art' was comprehensively reviewed in a Cold Spring Harbor Symposium volume. Subsequent years have witnessed a veritable explosion in the literature, not only in classical areas of tRNA research but also in new ones such as analysis of tRNA genes, tRNAs as primers of reverse transcriptase activity, and determination of tRNA tertiary structure.

It is thus more than timely for an overview of all these aspects of tRNA function. This book succeeds admirably in this task, by providing a number of reviews, all by leading authorities in the field. The introduction (by Zachau) serves to establish the subject in a historical perspective, as well as reminding us of the many questions still left unanswered. The impact of our knowledge of the tertiary structure of just one tRNA is well illustrated throughout the book, and not only by the chapter on its crystal structure and immediate implications (by Kim). In particular, Clark's chapter collating features of primary, secondary and tertiary structure provides a fascinating account of the generalisations and clues to function at the molecular level provided by the yeast phenylalanine tRNA crystal

structure. The essay by Crothers and Cole on conformational changes of tRNA in solution serves to provide a physically based viewpoint complementary to descriptions of structure in the crystalline state.

The contribution of Iglio and Cramer on tRNA synthetases and their substrate interactions, elegantly describes the current status in this area, to which Cramer's group have themselves made many significant contributions. The beginnings of understanding at the molecular level are also discussed by Pongs in a chapter largely concerned with ribosomal and mRNA recognition in relation to protein synthesis. Both these chapters clearly indicate the important directions to pursue in the future, difficult though they will be.

Other sections in this book are more concerned with biological topics. Thus, Altman himself reviews the area of tRNA biosynthesis, and with Körner and Feinstein he discusses tRNA-mediated suppression. Many other roles of tRNA are reviewed by LaRossa and Söll, Nishimura, in a chapter on modified nucleosides and isoaccepting tRNAs, suggests that many of these regulatory roles involve modified residues, in as yet unrevealed ways.

Throughout this book the sense of excitement still pervading many areas of transfer RNA study, come across very clearly. It can thus be recommended as a worthwhile and stimulating read for graduate and even advanced undergraduate students in molecular biology as well as for those workers more actively involved in the subject.

# announcements

## Meetings

27 May–1 June, **14th World Gas Conference of the International Gas Union**, Toronto (F. H. Ellins, Canadian Gas Association, 55 Scarsdale Road, Don Mills, Ontario M3B 2R3).

29 May–1 June, **Radioimmunoassay**, Brescia (Centro Congressi del Garda, Villa Alba, Gardone Riviera (Brescia) Italy).

8–10 June, **Multidisciplinary Aspects of Brain Tumour Therapy**, Brescia (Centro Congressi del Garda, Villa Alba, Gardone Riviera (Brescia) Italy).

12 June, **Weed Workshop '79**, Oxford (ARC Weed Research Organisation, Begbroke Hill, Yarnton, Oxford, UK).  
13–15 June, **Ultrasoft X-ray Microscopy**, New York (Conference Director, The New York Academy of Sciences, 2 East 63rd St, New York, New York 10021).

18–20 June, **Anion Transport in Epithelia, Isolated Cells and Cell Membranes**, New York (Conference Director, The New York Academy of Sciences, 2 East 63rd St, New York, New York 10021).

10–15 June, **Specialised Membrane Functions**, Rome (Prof. L. Masotti, Istituto di Chimica Biologica, Ospedale Maggiore, Via Cramsci 14, Parma, Italy).

18–22 June, **20th Advanced Course of Clinical Oncology**, Milan (Lucia Manfredi, Ufficio Attività Didattiche, Istituto Nazionale Tumori, Via G. Venezian, 1 20133 Milan, Italy).

18–21 June, **Metabolic Effects of Alcohol**, Milan (Nutrition Foundation of Italy, Via S. Pietro all'Orto 17 20121 Milan, Italy).

2–6 July, **Automatic Control in Space Symposium**, London (The Institute of Measurement and Control, 20 Peel Street, London W8, UK).

17–24 July, **2nd International Congress of Systematic and Evolutionary Biology**, Vancouver (University of British Columbia, Vancouver, Canada).

24–26 July, **6th International Symposium of Synthesis in Organic Chemistry**, Cambridge (Dr John Gibson, The Chemical Society, Burlington House, London W1, UK).

25–27 July, **Food Control in Action Symposium**, Guildford (Dr D. A. Rosie, Department of Food Science and Applied Biology, Polytechnic of the South Bank, Borough Road, London SE1, UK).

20–25 August, **3rd International Con-**

**ference on Surface and Colloid Science**, Stockholm (The Swedish Institute for Surface Chemistry, c/o Stockholm Convention Bureau, Strandvagen 7 c, S-114 56 Stockholm, Sweden).

2–6 September, **7th International Meeting of the International Society for Neurochemistry**, Jerusalem (Prof. S. Gatt, Department of Biochemistry, Hadassah Medical School, Hebrew University, P.O. Box 1172, Jerusalem, Israel).

2–7 September, **Regulation and Function of Neural Peptides**, Brescia (Marco Trabucchi, M.D., Ente Universitario Lombardia Orientale, Istituto di Farmacologia e Terapia, Via Valsabbina, 19, 25100-Brescia, Italy).

2–7 September, **10th International Hot Atom Chemistry Symposium**, Loughborough (Dr D. J. Malcome-Lawes, Chemistry Department, Loughborough Institute of Technology, Loughborough, Leicestershire, UK).

3–6 and 6–7 September, **Conference on Bio-medical Applications of Lasers and Lasers in Photomedicine and Photobiology**, Florence (Prof. R. Pratesi, Laboratorio di Elettronica Quantistica, Via Panciatichi 56/30, Firenze, Italy).

3–6 September, **EMAG '79**, Brighton (Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).

3–7 September, **Mass Spectrometry**, Swansea (Mrs S. Leclercq, The Chemical Society, Burlington House, Piccadilly, London W1, UK).

4–7 September, **Viral Enteritis in Humans and Animals**, Yvelines (Dr R. Scherrer, Station de Recherches de Virologie et d'Immunologie, 78850 Thiverval-Grignon, France).

9–14 September, **7th International Meeting of the International Society for Oncodevelopmental Biology and Medicine**, Guildford (A. M. Neville, Ludwig Institute for Cancer Research, The Haddow Laboratories, Sutton, Surrey, UK).

10–12 September, **4th Annual Symposium of the Uranium Institute**, London (Ms J. Murray, Uranium Institute, New Zealand House, Haymarket, London SW1, UK).

10–12 September, **Biennial Polymer Physics Conference**, Weybridge (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).

10–20 September, **International Symposium on Rift Zones of the Earth**, Jerusalem (Dr Zvi Garfunkel, Depart-

ment of Geology, Hebrew University of Jerusalem, Jerusalem, Israel).

10–13 September, **12th Annual Quantum Chemistry Conference**, Oxford (Dr P. J. Grout, Theoretical Chemistry Department, 1 South Parks Road, Oxford).

10–15 September, **International Anaesthesia Postgraduate Course**, Vienna (Vienna Medical Academy, Alser Strabe 4, A-1090 Vienna, Austria).

10–13 September, **Cellular Responses to Mutagens and Carcinogens**, Brighton (Prof. R. J. Cole, School of Biological Sciences, University of Sussex, Brighton, UK).

10–14 September, **EUCHEM Conference on Organic Free Radicals**, Cirencester (Dr J. F. Gibson, The Chemical Society, Burlington House, London W1, UK).

10–14 September, **Management Studies for R & D Chemists 1979**, Slough (Mrs S. Leclercq, The Chemical Society, Burlington House, London W1, UK).

10–14 September, **Inorganic Biochemistry**, Oxford (Mrs S. Leclercq, The Chemical Society, Burlington House, Piccadilly, London W1, UK).

16–21 September, **30th Annual Session American Association for Laboratory Animal Science**, Atlanta (Mr J. J. Garvey, AALAS, 2317 W. Jefferson Street, Suite 208, Joliet, Illinois 60435).

16–26 September, **Advances in Radiation Protection and Dosimetry and Medicine**, Sicily (Prof. V. Perez-Mendez, Building 50, Lawrence Berkeley Laboratory, University of California, Berkeley, California 94720).  
17–21 September, **Advances in Crop Production and Crop Protection**, Reading (Dr J. M. Thresh, Association of Applied Biologists, East Malling Research Station, Maidstone, Kent, UK).

18–20 September, **2nd World Filtration Conference**, London (Dr Albert Rushton, University of Manchester Institute of Science and Technology, Manchester, UK).

19–21 September, **4th National Quantum Electronics Conference**, Edinburgh (Dr B. S. Wherrett, Physics Department, Heriot-Watt University, Edinburgh, UK).

1–4 October, **B Cell Differentiation and Idiotypes**, Paris (Inserm Conferences, 101 rue de Tolbiac, 75645 Paris Cedex 13, France).

1–5 October, **15th Congress of the International Union of Game Biologists**, Dublin (Fergus O'Gorman, 44 Northumberland Road, Dublin 4, Ireland).

20–26 September, **World Book Fair on Telecommunications and Electronics**, Geneva (Mr A. G. El-Zanati, 18 quai Ernest-Ansermet, CH-1211 Geneve 4, Switzerland).

23–26 September, **International Symposium on Inborn Errors of Metabolism in Humans**, Interlaken (Mrs Sonja Wyss, Medizinisch-chemisches Institut, Universität Bern, Buhlstrasse 28, CH-3000 Bern 9, Switzerland).

23–27 September, **Gene Transfer and Functional Analysis in Somatic Cells**, Paris (Inserm Conferences, 101 rue de Tolbiac, 75645 Paris Cedex 13, France).

24–28 September, **Growth and Properties of Metal Clusters: Applications to Catalysis and the Photographic Process**, Villeurbanne-Lyon (Société de Chimie Physique, 10 Rue Vaquelin, Paris 5).

24–28 September, **3rd International Reunion for the History of Nautical Science and Hydrography**, London (The Conference Officer, National Maritime Museum, Greenwich, London, UK).

25 September, **Materials Selection for Wear Resistance**, Uxbridge (The Meetings Secretary, The Institution of Metallurgists, Northway House, Whetstone, London N20, UK).

25–27 September, **Organization of Macromolecules in the Condensed Phase**, Cambridge (Mrs Y. A. Fish, Faraday Division, The Chemical

Society, Burlington House, Piccadilly, London W1, UK).

25–26 September, **Hydrocarbons in Biotechnology**, Canterbury (Ms I. McCann, Conference Department, Institute of Petroleum, 61 New Cavendish Street, London W1, UK).

26 September, **Computer Modelling in Ultrasonics**, London (Dr L. J. Bond, Physics Department, City University, Northampton Square, London EC1, UK).

27–28 September, **Workshop on The Uses of Oestrogens as Carriers of Cytotoxic Agents in Hormone Receptive Tumours**, Diepenbeek (Dr J. Raus, Dr L. Willems-Institut, Universtaie Campus, B-3610 Diepenbeek, Belgium).

28–29 September, **Steroid Induced Uterine Proteins**, Marburg (Dr M. Beato, Inst. Physiol. Chemie, 3550 Marburg, Germany).

7–11 October, **Genetic Control and Diseases**, Paris (Inserm Conferences, 101 rue de Tolbiac, 75645 Paris Cedex 13, France).

22–24 October, **19th Annual Hanford Life Sciences Symposium**, Richland (Mrs J. A. Rising, Biology Department, 331 Building, Batelle, Pacific Northwest Laboratories, Richland, WA 99352).

30 October–2 November, **Separation Science and Technology for Energy Applications**, Gatlinburg (Mr A. P.

Malinauskas, Oak Ridge National Laboratory, PO Box X, Oak Ridge, Tennessee 37830).

8–10 November, **International Symposium on Trisomy 21**, Rapallo (Prof. M. Fraccaro, C.P. 217, I-27100 Pavia).

8–10 November, **12th Danube Symposium on Neurological Sciences**, Innsbruck (Vienna Medical Academy, Alser Strabe 4, A-1090 Vienna, Austria).

8–10 November, **Albert Einstein as an Intercultural and Interdisciplinary Phenomenon: His Influence in all Fields of Thought**, New York (University Centre for Cultural and Intercultural Studies, Hofstra University, Hempstead, New York 11550).

12–16 November, **World Conference 3 on Breeding Endangered Species in Captivity**, San Diego (Ms J. Hammer-shoy, Conference Coordinator, San Diego Zoo, PO Box 551, San Diego, California 92112).

23–24 November, **Latest Therapy of Urethral Stricture in Male; Indication, Technique, Postoperative Care and Late Results with Staghorn Calculi**, Vienna (Vienna Medical Academy, Alser Strabe 4, A-1090 Vienna, Austria).

27–30 November, **On Protection of Workers against Noise**, Dresden (Organisationsburo, Postchließfach 105, DDR-8020, Dresden).

## APPOINTMENTS VACANT

### STRUCTURAL MOLECULAR BIOLOGIST

Position now available in the Biology Department of Brookhaven National Laboratory for a structural molecular biologist with considerable experience in instrumentation in the field of small angle scattering. The appointment is to the Scientific Staff. The scientist will be involved in the development of the Brookhaven National Laboratory Synchrotron facilities for use in small angle scattering experiments.

Applicants should submit a curriculum vitae (including a list of publications) and the names of three references to:

Dr. Benno P. Schoenborn  
Biology Department  
Brookhaven National Laboratory  
Associated Universities, Inc.  
Upton, Long Island, NY 11973

Equal Opportunity Employer  
m/f

**BROOKHAVEN NATIONAL LABORATORY**

### THE QUEEN'S UNIVERSITY OF BELFAST RESEARCH ASSISTANT

Marine Biology Station, Portaferry

This project involves a study of the effects of light fluctuations on marine phytoplankton photosynthesis and growth. The post, tenable for three years, will be financed by the N.E.R.C. Commencing salary £3,384 on a scale (under review) rising to £3,885 per annum plus U.S.S.

Further particulars may be obtained from Dr G. Savidge, Queen's University of Belfast, Marine Biology Station, Portaferry, Co Down BT22 1PF, Northern Ireland.

Applications, giving the names and addresses of two referees, should be sent to the Personnel Officer, The Queen's University of Belfast, BT7 1NN, Northern Ireland. Closing date: May 31, 1979.

688(A)

### UNIVERSITY COLLEGE DUBLIN DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a post as RESEARCH TECHNICIAN in the above Department. The successful applicant will assist in a special project sponsored by Nordic Cold Storage Ltd., should hold N.C.E.A. or I.M.L.S. qualifications and preferably with subsequent laboratory experience.

Appointment will be on an annual basis for up to three years on a scale:

Technician £71.67 by four increments—£82.35 per week

Senior Technician £85.31 by four increments—£96.78 per week at a level commensurate with qualifications and experience.

Applications giving details of qualifications and experience and the names of two referees should be forwarded before May 31, 1979 to one of the following addresses:

The Secretary, Department of Biochemistry, University College, Belfield, Dublin 4 or Mr W. J. A. Fearn, 1, The Sanctuary, Westminster SW1P 3JT, London, England.

713(A)

### ATMOSPHERIC SCIENTIST

to work in well-equipped laboratory, with a team on the atmospheric planetary boundary layer. The team is involved at a fundamental level in all aspects of the lower troposphere, and work in progress includes airborne measurement studies and theoretical modelling of the surface layer, clouds and precipitation. Requires Ph.D., or equivalent, in related area. Must be skilled with computer programming, numerical methods and mathematical analysis. A good background in physical understanding is important and ability to participate in all aspects of the programme is desirable. The level of appointment is dependent upon ability and qualifications, and opportunities exist for contributing to training graduate students and lecturing. Minimum starting salary \$18,000 plus liberal benefits. Send resume postmarked by June 30, 1979 to Personnel Department, Desert Research Institute, University of Nevada System, P.O. Box 60220, Reno, Nevada 89506. Affirmative Action/Equal Opportunity Employer.

W102(A)

### UNIVERSITY OF CAMBRIDGE DEPARTMENT OF GENETICS RESEARCH ASSISTANT

A position is available, from October 1, 1979, for 3 years, on a research project funded by the Science Research Council, for a research assistant; experience in Drosophila genetics would be an advantage but not essential. Salary at age 24, £3,883, under review.

Further details may be obtained from Dr M. Ashburner to whom applications, with the names of two referees, should be sent to reach him by June 30, 1979, Department of Genetics, Downing Street, Cambridge CB2 3EH.

708(A)

### UNIVERSITY COLLEGE CARDIFF

Applications are invited for the post of

### RESEARCH ASSISTANT

in the Department of PHYSIOLOGY to work on the Physiology of the Nasal Mucosa of the Domestic Pig. The research is supported by an A.R.C. grant for a period of three years, and will involve experiments to study the roles of the autonomic nervous system and endocrine system in the regulation of the nasal mucosa. More information about the project will be provided by Dr R. Eccles, Department of Physiology, University College, P.O. Box 78, Cardiff CF1 1XL. Salary range: Within R. & A. 1A £3,883 to £4,882 per annum. Duties to commence September 1979.

Applications (two copies), together with the names and addresses of two referees, should be forwarded to the Vice-Principal (Administration) and Registrar, University College, P.O. Box 78, Cardiff CF1 1XL. Closing date June 7, 1979. Reference 1979.

753(A)

### THE BRITISH COUNCIL

invites applications for the following posts:

1. Lecturer in Mineral Economics or Economics Geology
2. Lecturer in Rural Sociology (Brazil)

Federal University of Paraíba, Joao Pessoa (required for August 1979)

To lecture to undergraduate and postgraduate students and for post (2) to develop research activities.

Qualifications: PhD with at least 2 years' university teaching experience or MSc. with 5 years' relevant experience (10 years preferred). Age range over 30. A knowledge of or willingness to learn Brazilian Portuguese is necessary. Salary: Cr\$33,000 to Cr\$41,000 per month according to qualifications. (Cr\$49.04 equals £1 at 24/4/79). Benefits: 2-year guaranteed contract.

Return fares are paid. Local contracts are guaranteed by the British Council. Please write briefly stating qualifications and length of appropriate experience, quoting relevant reference number and title of post for further details and application form to The British Council (Appointments) 65 Davies Street, London W1Y 2AA.

698(A)

### BRITISH CELLOPHANE LIMITED

### RESEARCH INTO POLYPROPYLENE FILMS

An imaginative optical physicist is required at the Company's principal site in Bridgwater, Somerset. To work on the morphology and structure of oriented polypropylene films.

This is an opportunity to become involved in a research programme seeking fundamental information on which to base a new generation of packaging films.

The successful candidate will be expected to initiate or maintain liaison with University staffs working in related fields.

There will be opportunities for publication on some of the theoretical aspects of the work, and for other aspects it is expected the Company will seek patent coverage.

Applicants must be self-motivating and have a first class degree plus relevant research experience in the academic or industrial fields.

An attractive salary is offered and the conditions of service are those normally associated with a progressive company. These include extensive technical library facilities and a contributory staff pension scheme. Assistance with relocation expenses can be given where necessary.

Please apply in writing or by telephone to Mr R. C. Rudd, Group Personnel Department, British Cellophane Ltd., Bath Road, Bridgwater, Somerset TA6 4PA. Tel: 0278 4321 ext. 558.

749(A)

**NATIONAL INSTITUTE FOR RESEARCH IN  
DAIRYING  
(UNIVERSITY OF READING)**

**NUTRITION DEPARTMENT**

A graduate is required to participate in a programme of fundamental research into the physiological role of trace nutrient binders in milk and other foods. The work will be mainly concerned with the isolation, characterisation and comparative biochemistry of binding substances from milks of different mammalian species, in particular from bovine and human milk. The appointed person will work within a small group studying binding substances and will be expected to initiate and execute experimental work with a minimum of supervision.

Qualifications: First or Upper Second class Honours Degree in biochemistry or recently qualified Ph.D. Applicants with experience in protein chemistry and enzymology will be at an advantage.

Appointment will be as Scientific Officer (£2,839 to £4,415) or Higher Scientific Officer (£4,101 to £5,448) according to qualifications and experience. At least two years' relevant postgraduate experience is required for appointment as H.S.O. Non-contributory superannuation scheme.

Application forms are obtainable from the Secretary, NIRD, Shinfield, Reading RG2 9AT. Quote reference 79/15. 595(A)

**Division of Hormones**

**Postdoctoral  
Scientist**

Required to work on a three-year project as part of a team and to collaborate with other groups engaged on studies of the mechanism of action and secretion of hormones; for studies on the mechanism of coupling between hormone receptors and adenylate cyclase systems in cell membranes, using cell fusion techniques.

A knowledge of biochemical endocrinology, cell membrane systems and/or cell fusion processes would be an advantage.

Salary in accordance with age and experience, on university lecturing scales.

Application form and further details from The Personnel Section, NIBSC, Holly Hill, Hampstead, London NW3 6RB. Tel: 01-435 2232, ext. 200. (Please quote reference number HO/277).

**NIBSC**

National Institute for Biological Standards and Control

**IMMUNOPHARMACOLOGIST**

The Research Unit of Organon Laboratories Limited is an integral part of the Scientific Development Group of Organon International, a major international pharmaceutical company based in the Netherlands.

Applications are invited for this major appointment in our Biochemistry R. & D. Department. This department is responsible for long term research aimed at the development of new drugs for treating chronic inflammatory diseases with emphasis on the involvement of the immune response. This is a challenging post working as part of a young and enthusiastic interdisciplinary team within a rapidly developing area of research.

Suitable candidates will already be working on the immunological aspects of chronic inflammation and have a Ph.D degree with several years postdoctoral experience.

The successful candidate will be expected to maintain and develop his expertise and reputation in the field by attendance at scientific meetings and by publication of his research results.

The initial salary will be based on qualifications and experience and will be commensurate with the responsibilities of the position. Conditions of employment are in keeping with good modern practice and assistance with relocation expenses will be available in appropriate cases.

Applications should be sent to the Personnel Manager, Organon Laboratories Limited, Newhouse, Lanarkshire, ML1 5SH. 730(A)

**INSTITUTE OF DENTAL SURGERY  
BRITISH POSTGRADUATE MEDICAL FEDERATION  
UNIVERSITY OF LONDON**

Applications are invited for the post of  
**HEAD OF DEPARTMENT/SENIOR LECTURER**  
in the Department of Microbiology.

Previous dental experience is not essential, but applicants should have a postgraduate degree in the medical/dental or biological sciences and research experience. If appropriate, the successful candidate will be given honorary consultant status by the associated Eastman Dental Hospital.

Salary will be on one of the following scales:

Non-clinical £7,506 to £9,263 plus £502 L.W.

Clinical £6,982 to £9,670 plus £354 L.W.

Clinical with honorary consultant status £9,528 to £12,084 plus £354 L.W.

(Salary awards pending on scales).

Applications and/or enquiries to Mrs C. L. Fox, Deputy Secretary, Institute of Dental Surgery, Eastman Dental Hospital, 256 Gray's Inn Road, London WC1X 8LD. 700(A)

**LIVERPOOL POLYTECHNIC  
Department of Chemistry and Biochemistry  
RESEARCH ASSISTANT  
£2511—£2697**

Applications are invited for an L.E.A. research assistant to work with Dr. D. Billington on biochemical mechanisms involved in mammalian bile formation, with particular reference to hepatic bile salt transport.

Application forms and further particulars may be obtained from The Personnel Office, Richmond House, 1 Rumford Place, Liverpool L3 9RH, or by telephoning Dr. Billington on 051-207 3581 Ext. 32.

Please quote reference L.P.284.

**CSIRO****AUSTRALIA**

# Division of Computing Research

Canberra A.C.T.

**General Manager (4 positions)****Section Leader (6 positions)****Research Scientist (several positions)****Experimental Officer (System Specialist) (4 positions)****General**

The Commonwealth Scientific and Industrial Research Organisation (CSIRO) is a statutory authority established in 1949 by act of the Australian Parliament. The functions of CSIRO include carrying out and facilitating the application and utilisation of scientific research to assist Australian industry, furthering the interests of the Australian community, and contributing to the achievement of Australian national objectives.

The Division of Computing Research (DCR) is responsible for the research, development, maintenance and operation of systems and equipment used by the national computing facility, named CSIRONET. The facility serves CSIRO, Government Departments and Instrumentalities, and other approved users. CSIRO, through DCR, is also called on to advise Government and others on computing policy and requirements. It has an annual revenue in excess of \$6 million, and employs about 140 staff. The functions of DCR have recently been reviewed, leading to the restructuring of the Division into four Branches to meet the computing needs of its users as these requirements increase in quantity and complexity and change in direction. Each Branch comprises a number of research and development Sections and/or support Sections.

Each research and development Section comprises a research leader, at least one other research scientist, together with an appropriate support staff. The Sections solely engaged in support or co-ordination are not led by research staff. With few exceptions it is expected that the members of a Section will be located together. Each present or proposed Section is placed in a capital or large provincial city which includes at least one university and other tertiary educational or scientific institution.

Access to the CSIRONET host computers is provided by about 650 interactive and 250 batch devices connected to a packet switching network involving 80 minicomputer nodes. Internode lines operate at speeds up to 48 kilobits per second. During prime shift about 40 megabytes per hour are transmitted through the network. Special purpose nodes are implemented, or planned to provide spool, monitor, sentry, gateway and other distributed functions. A resource sharing network using Network Systems adaptors driving coaxial cables operating at 50 megabits per second is being implemented to serve the host computers. The principal general purpose host at present is a maximum configuration Control Data Cyber 76, supported by 7 GB (gigabytes) of disc storage. A Cyber 17X supported by 2 GB of disc and 32 GB mass storage will be installed for developmental work. A Facom M190 supported by 2.4 GB is used as a research and development vehicle. Special purpose hosts include an Information International COMp80 phototypesetting and (micro) graphics system, a COMTAL/PDP11 image processing system, a VM system controlling a Calcomp automatic tape library, and other development systems.

**Duties:****General Managers**

Under the Chief of the Division, the General Managers are the most senior officers of DCR, and are responsible for policy development, and for the management of the research and development activity of a Branch of the Division.

A General Manager may be required to deputise for the Chief of Division. Frequent interstate travel is necessary.

**The four Branches are:**

1. Computing Systems Branch. Activities include research and development and the maintenance of the Cyber 76 Scope system, the NOS operating system, and VM system, and OSIV F4 system, mass storage systems, and distributed processing systems.

2. Information Systems Branch. Activities include research and development in distributed data base systems, information retrieval, computer security, simulation and system analysis, computational methods, classification methods, program structures and mathematical programming.

3. Peripheral Systems Branch. Activities include research and development of VLSI architecture and other hardware projects, picture processing, graphics, micrographics, the research, development and maintenance of packet switching and resource sharing networks, and of network performance measuring tools.

4. Co-ordination and Support Branch. Responsibilities include the co-ordination of the research, development and system maintenance

activities of the Division. Other activities of this Branch are system documentation, user assistance, applications support, operations, business systems, accounting, administration, site management and the Divisional library.

**Section Leaders**

Under the broad direction of a General Manager, a Section Leader is responsible for the planning and conduct of a particular research and development program, including maintenance of products and systems developed by the Section, and for consultation with users and organization of workshops and seminars.

**Section Leaders are required for:**

1. Information Retrieval (Melbourne)
2. Stochastic Simulation (Sydney)
3. VLSI Architecture (Adelaide)
4. Computational Method (Brisbane)
5. Program Structures (Perth)
6. Mathematical Programming (Hobart)

**Research Scientist**

Is required to initiate and undertake a research and development program in a particular field. Some responsibility for activities of other staff may also be required. Vacancies exist in the above six sections, and also in:

7. Operating Systems (Canberra)
8. Classification Methods (Townsville)
9. Continuous Simulation (Brisbane).

**Experimental Officer (System Specialist)**

Under the broad direction of a General Manager, is the leader of a number of professional and support staff in a Section responsible for the maintenance of a major computing or support system in one of the following fields:

10. Computer security (Canberra)
11. NOS system (Canberra)
12. VM system (Canberra)
13. User services (Canberra)

**Qualifications**

For appointment to positions of General Manager, Section Leader or Research Scientist, a Ph.D. or equivalent qualification in the field of Computing or Information Science is required. Applicants for the positions of General Managers and Section Leaders should have had extensive experience relevant to the position concerned, supported by evidence of management ability at an appropriate level.

For appointment as Experimental Officer, a degree or equivalent qualification in Computing or Information Science is required, together with extensive professional experience relevant to the position concerned.

**Salary**

Successful candidates would be appointed within the following salary ranges:

General Manager: \$A27,790-\$A30,530 p.a. with consideration of appointment at higher level for an outstanding applicant.

Section Leader: \$A23,247-\$A30,530 p.a.

Research Scientist: \$A15,422-\$A22,405 p.a.

Experimental Officer: \$A17,800-\$A21,702 p.a. with consideration of appointment at a higher level for an outstanding applicant with proven management ability of a high order.

**Conditions**

Conditions of service include participation in the Superannuation Scheme, long service and sick leave benefits and four weeks annual leave. Appointee's fares, removal expenses and an allowance until permanently housed may be paid.

**Tenure**

Indefinite or fixed term appointments may be negotiated, both of which carry Superannuation benefits.

**Applications**

Applications in duplicate stating full personal and professional details, and the names of at least two referees, and quoting reference number 900/345 and the position in which interested should reach: The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 9th June 1979.

Applications in USA and Canada should be sent to: The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, USA.

## MARINE RESOURCES ASSESSMENT SCIENTISTS

Salary: \$16,500 to \$39,517 (depending on  
qualifications)

Fisheries and the Environment  
Fisheries Management  
St. Andrew's, New Brunswick

Two positions are available at the St. Andrew's Biological  
Station, to develop and evaluate resource inventory methods  
for pelagic and groundfish stocks in Eastern Canadian waters  
as part of the stock assessment process.

### SECTION HEAD, RESOURCE INVENTORY (109-025-017)

Ref. No: 79-NCRSO-32-150 (N)

The senior position of the two vacancies is for the leader of the  
Resource Inventory Section which has a staff complement of  
about twenty. In addition to coordinating the development of  
resource inventory programs, the successful candidate will  
manage the fish aging service of the division; will coordinate  
the fish sampling activities and computer services of the  
section; and, will collect data on oceanographic parameters.

### RESEARCH SCIENTIST, FISH SURVEYS (109-037-023)

Ref. No: 79-NCRSO-32-149 (N)

The junior position is for a scientist to conduct research  
primarily on the design and development of pelagic fish  
survey techniques.

### QUALIFICATIONS

Applicants for either of the above positions must possess a  
PhD in quantitative fish biology with specific training in  
statistical methodology. A lesser degree coupled with  
evidence of research experience and productivity which is  
equivalent to a doctorate is also acceptable.

For the junior position, experience in applied fisheries  
research and evidence of ability in program management  
are desirable.

For the senior position, applicants must have published a  
substantial number of scientific papers and be recognized as  
experts in this field at the national level. Experience in program  
management is essential for this position.

Knowledge of English is essential.

### How to Apply

Send your application form and/or résumé to:

D. E. Fraser, Staffing Officer  
National Capital Region Staffing Office  
Public Service Commission of Canada  
Ottawa, Ontario K1A 0M7  
Closing Date: May 31, 1979

Please quote the applicable reference number at all times. 746(A)

## SENIOR BIOLOGIST £5,682—£6,750 p.a.

male or female, with good honours degree in biology, to  
undertake routine macro- and micro-biological exami-  
nations, including appraisals of algal status of raw water  
reservoirs, macro-biological evaluations of reservoir  
marginal areas, of mains infestations and consumer com-  
plaint samples. In addition research and development  
projects are actively encouraged.

## ASSISTANT BIOLOGIST £4,179—£4,476 p.a.

recently qualified graduate, male or female, to assist the  
Senior Biologist. An excellent opportunity for acquiring  
wide-ranging experience within the water supply industry.

Both posts would initially be based at Lichfield, Staffs,  
but will be moving to new laboratories presently being  
constructed at Walsall, West Midlands. Reasonable re-  
location expenses payable.

Please write by May 24, to

The Chief Engineer,  
The South Staffordshire Waterworks Co.,  
50 Shepcote Street, Birmingham B16 8AR. 705(A)

**PLYMOUTH  
POLYTECHNIC**

### RESEARCH ASSISTANTS required for the following areas of study: School of Maritime Studies ASTRONOMY

To analyse data connected with the  
magnetic field of the Milky Way.  
Applicants should have a good honours  
degree in Physics, Mathematics or  
Astronomy. An interest in computing  
and astronomical data analysis is  
essential.

School of  
Environmental Sciences  
LITHOSTRATIGRAPHY,  
BIOSTRATIGRAPHY,  
SEDIMENTOLOGY AND  
PALAEOLOGY OF THE  
UPPER GREENSLAND.  
THE UPTAKE OF POLY-  
NUCLEAR AROMATIC  
HYDROCARBONS IN  
ESTUARINE FOOD WEBS.  
DISPERSAL AND HOST-  
PLANT FINDINGS IN DELTA  
BRASSICAE IN RELATION  
TO AGRICULTURAL  
PRACTICE.  
THE MIGRANT POPULATION  
OF PLYMOUTH IN THE  
19TH CENTURY.  
CARBON AND COKE  
REACTIVITY IN ZINC-LEAD  
BLAST FURNACE PRACTICE.  
STRUCTURAL AND  
GEOTECHNICAL STUDIES  
OF PLYMOUTH LIMESTONE.

Candidates for predoctoral assistant-  
ships should have a good first degree  
in a relevant discipline.

Research Assistants are normally  
required to register for a higher  
degree, although postdoctoral appli-  
cants will be considered. Appointments  
are for a period of two years,  
normally commencing September 1,  
with a possibility of a third year  
(Fixed term contracts). Salary will be  
£3,192 for postgraduates or £3,468  
postdoctoral (or equivalent) with  
annual increments of £138.

Application forms to be returned by  
Friday, June 8, 1979 can be obtained  
with further particulars (please state  
which project) from the Personnel  
Officer, Plymouth Polytechnic, Drake  
Circus, Plymouth PL4 8AA. 701(A)

## UNIVERSITY OF CAMBRIDGE

Applications are invited for the  
office of

### UNIVERSITY LECTURER IN THE DEPARTMENT OF PHARMACOLOGY

from those working in any area of  
experimental pharmacology, and  
applicants with experience in mem-  
brane current fluctuation analysis are  
particularly encouraged.

The initial appointment will be for  
three years from October 1, 1979 with  
the possibility of reappointment to  
the retiring age. The pensionable  
stipend for a University Lecturer will  
be on a scale of £5,367 rising by  
twelve annual increments to £8,257 a  
year (under review), with initial  
placing above the minimum where  
appropriate. There is no grade of  
Senior Lecturer. A grant is made  
towards removal expenses.

Candidates should send 12 copies of  
their application together with the  
names of not more than three referees  
to Mr G. R. ANDERSON, General  
Board, Office, The Old Schools,  
Cambridge CB2 1TT, from whom  
further information can be obtained,  
to arrive not later than June 1, 1979.  
751(A)

## ST. GEORGE'S HOSPITAL MEDICAL SCHOOL (University of London)

### LECTURER/SENIOR LECTURER IN PHARMACOLOGY

The appointment is tenable from  
September 1, 1979. The Department  
of Pharmacology has a strong interest  
in the post-synaptic action of neuro-  
transmitters both in the brain and the  
peripheral nervous system using a  
variety of electrophysiological tech-  
niques. Although preference may be  
given to candidates with an interest  
in biochemical aspects of drug receptor  
interactions or transmitter release,  
strong candidates from all disciplines  
will be considered. Salary ranges  
£3,975 to £8,250 (Lecturer) and £7,980  
to £9,885 (Senior Lecturer). (Both  
ranges under review). In addition  
London allowance £502 per annum.

Further particulars available from  
the Establishment Officer, St George's  
Hospital Medical School, Cranmer  
Terrace, London SW17 0RE, to  
whom applications, with the names of  
three referees, must be sent to arrive  
by June 4. 748(A)

# Section Head— Inhalation Toxicity

## ICI Central Toxicology Laboratory

This Laboratory provides advisory and experimental services to ICI Limited, for the control of toxic hazards in manufacturing processes and in other fields of growing importance, such as the development of pesticides and food additives. Emphasis is placed on improving and assessing methods for studying the biological effect of foreign compounds and upon understanding mechanisms of toxicity. The Provision of toxicological information, prior to product clearance and registration in many countries, is a major activity undertaken by the Laboratory on behalf of the ICI group.

We currently have a vacancy for someone to head our Inhalation Toxicity Section. The job holder will be responsible for managing approximately 18 people who are involved in the provision of a facility to assess any potential health risks through inhalation of chemicals and particulates. The job holder is expected to contribute to the overall management of the Laboratory, and to formulate the correct technical policy for the Section whilst ensuring that results produced are reliable.

The successful candidate will have post-doctoral experience of research on the pulmonary system together with proven ability in managing multi-disciplinary project teams. It is unlikely that any candidate below 30 years of age will have accumulated sufficient experience.

The Laboratory is two miles south of the village of Alderley Edge on the main road (A34) between Manchester and the Potteries on a 300 acre site which the Laboratory shares with ICI's Pharmaceuticals Division. Alderley Edge is less than 20 miles from Manchester and in addition to the well-wooded Cheshire countryside which surrounds it, Alderley is within easy reach of the Derbyshire Peak District, the Lake District and the North Wales Coast. Staff working at Alderley live over a wide area but mainly in the Macclesfield and Alderley Edge/Wilmslow area.

In addition to salary ICI also operate a Productivity Bonus and Profit Sharing Scheme.

Anyone interested in applying for this vacancy (either male or female) should telephone or write (quoting reference IT/SH/SCC) to:-

Miss S. C. Carson, Personnel Officer,  
ICI Ltd., Central Toxicology Laboratory,  
Alderley Park, Nr. Macclesfield,  
Cheshire.  
Phone: Alderley Edge 582711,  
extension 144.

Overseas candidates should only apply if they have a planned visit to the UK within the next two months.  
Closing date for applications: 31st May 1979.

719(A)

### UNIVERSITY OF KHARTOUM—SUDAN

Applications are invited for the following posts in the FACULTY OF EDUCATION:-

#### DEPARTMENT OF

#### CHEMISTRY (Three Posts)

LECTURER in Physical Chemistry  
—Theoretical Chemistry (wave mechanics—theories of bonding—Spectroscopy).

LECTURER in Physical Chemistry  
—Thermodynamics and related fields.

LECTURER in Inorganic Chemistry.

#### DEPARTMENT OF PHYSICS

Four LECTURERS in Classical and Modern Physics.

Salary scale (exclusive of cost of living allowance) £S1,500 to £S3,500 per annum (£S1 equals £1.20 sterling). The British Government may supplement salaries in range £3,894 to £4,542 per annum (sterling) for married appointees (reviewed annually and normally free of tax) and provide children's education allowances and holiday visit passages. Family passages; baggage allowance; superannuation scheme; unfurnished accommodation available; various allowances. Detailed applications (two copies) with curriculum vitae and naming three referees to be sent direct to Acting Personnel Secretary, University of Khartoum, P.O. Box 321, Khartoum, Sudan by June 28, 1979. Applicants resident in the U.K. should also send one copy to: Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 760(A)

**PLYMOUTH  
POLYTECHNIC**

#### SCHOOL OF ENVIRONMENTAL SCIENCES

### LECTURER II ECOLOGY

**SALARY: £4,101 to £6,558**

To organise and take part in undergraduate courses in marine, freshwater and/or terrestrial ecology.

Should be honours graduate in Biology or environmental sciences with a strong ecological background and a Ph.D. or equivalent research experience.

Opportunity to develop special teaching interests in honours degree options and/or M.Sc. in applied Fish Biology. Further research will be encouraged.

Application forms to be returned by **Friday June 8, 1979**, can be obtained with further particulars from the **Personnel Officer, Plymouth Polytechnic, Drake Circus, Plymouth PL4 8AA.**

761(A)

### North East Surrey College of Technology

Reigate Road

Ewell Surrey KT17 3DS

Principal: B. Haynes BSc DipEd CChem  
FRIC

## HEAD OF THE SCIENCES

The Governors wish to appoint a successor to the late W. C. A. Hards BSc CChem FRICS as Head of the Department of The Sciences with effect from September 1, 1979 or as soon as possible thereafter.

Salary: Burnham Head of Department (Grade IV) £7,941—£8,901 (under review).

Forms of application and further information about the post can be obtained from the Vice-Principal at the above address to whom applications should be returned by June 15, 1979.

**SURREY  
COUNTY COUNCIL**

# Research Group Leader

## Pyrometallurgy Research Group

# Research Staff

### Research Group Leader

The Institute's Pyrometallurgy Research Group is based at the University of the Witwatersrand and is linked direct with the Process Development Division. The Group does a considerable proportion of the longer term research work and enjoys close interaction with the Division. Applicants should possess the following qualifications:

- (i) a research degree in an appropriate discipline.
- (ii) experience in high temperature extractive metallurgy.
- (iii) experience in the supervision of graduate students or graduate personnel, or both.
- (iv) the ability and perspective to handle a number of different projects that are being conducted concurrently.
- (v) sufficient industrial knowledge to interact and communicate with representatives of industry, and
- (vi) sufficient experience to warrant appointment at the level of Principal Scientist, or preferably, Chief Scientist.

### Research Staff

The Institute is looking for research staff to work on projects covering a wide field in minerals and metals. Applicants should be in possession of a research degree in chemical engineering, extractive metallurgy, instruments or electronic engineering, analytical chemistry, industrial or pure chemistry, material science, minerals processing, or a related field.

Post-graduate experience will be a recommendation, but is not essential. Benefits include a pension scheme, medical and a housing-subsidy scheme, 5-day working week, generous leave privileges (in addition to normal vacation leave, the Institute closes for the period between Christmas and New Year), flexitime, subsidised cafeteria facilities, sports facilities such as squash, tennis, swimming, snooker, etc. and an annual leave bonus.

There are possibilities for advanced studies at universities, with substantial bursaries from the Institute.

The Institute will pay the fares to South Africa of the applicant and his family, contribute to removal expenses, and grant a settlement allowance under certain conditions. Please apply giving full details of age, qualifications, experience, etc. to:

The Head: Personnel, National Institute for Metallurgy,  
Private Bag X3015, Randburg 2125, South Africa.

**National Institute for Metallurgy**

727(A)

## UNIVERSITY OF LIVERPOOL

### DEPARTMENT OF VETERINARY PATHOLOGY

### TECHNICIAN

to provide an efficient technical service in this department which is responsible for veterinary pathology, microbiology and immunology. Duties include supervising and training technical staff, ordering equipment and supplies and maintaining appropriate accounts and records. The successful candidate will also be responsible for technical services to ensure the smooth running of undergraduate teaching courses and advice to academic and other staff on specialised techniques and apparatus. Candidates must have had a minimum of 13 years laboratory experience, an APMIS or equivalent appropriate qualification.

Salary within the range £5,172 to £5,625 per annum.

Application forms may be obtained from The Registrar, The University, P.O. Box 147, Liverpool L69 3BX. Quote Ref: RV/585/N. 695(A)

## UNIVERSITY OF SOUTHAMPTON

### DEPARTMENT OF BIOLOGY

Research Technician (biological sciences) required to support a research project aimed at evaluating the potential of fallow deer as farm animals. The post will involve full day to day running of feeding trials based at the Hampshire College of Agriculture, Sparsholt, Winchester.

Previous experience in the handling and management of large animals would be an advantage and applicants should hold a current driving licence. Minimum qualifications O.N.C./D.C. equivalent in science subjects (including biology) but graduates in appropriate disciplines are welcome to apply.

The appointment which is to be filled from August 1, 1979 will be for one year in the first instance with the possibility of renewal for a second year commencing with a salary of £2,757 per annum on grade 2B scale.

Applications giving date of birth, details of qualifications and experience and the names and addresses of two referees should be sent to Mr C. N. Saul, The University, Southampton SO9 5NH by June 1, 1979, quoting reference number 541/T/N. 741(A)

## DEPARTMENT OF GEOLOGY

### UNIVERSITY OF WINDSOR

has an opening at the rank of Assistant Professor, with specialisation in one or a combination of the following fields: Engineering Geology, Geotechnical Engineering, Structural Geology, Mining Geology or other applied disciplines. The position is a two-year appointment with review at the end of that period. It involves undergraduate- and graduate-level instruction, as well as conducting research programmes. Applicants should hold or anticipate a doctorate degree. Salary will be in the order of \$20,000 per year, depending on teaching, industrial and/or research experience. The position will commence as soon as possible, preferably September 1, 1979.

An application including a curriculum vitae and names of three referees should be sent to: Dr R. K. Jui, Chairman, Department of Geology, University of Windsor N9B 3P4. W104(A)

## QUEEN ELIZABETH COLLEGE

### Kensington

### (University of London)

### LECTURER IN FOOD SCIENCE

Applications are invited for the post of Lecturer in Food Science. Applicants will be expected to have an appropriate background in the Natural or Applied Sciences, preferably with research experience in an area of Food Science. The successful applicant will be required to teach some unit courses in Food Science to different years of the degree course and to undertake research. External contacts will be encouraged. Industrial or other relevant experience would be an advantage, and placing on the salary scale will reflect both qualifications and experience. Salary scale (under review) £3,909 to £7,754 per annum plus London Allowance of £502 per annum.

Apply to the College Secretary, Queen Elizabeth College, Campden Hill Road, London W8 7AH, from whom further particulars and an application form may be obtained. Closing date: June 8, 1979. 729(A)

## HARVARD MEDICAL SCHOOL

### NEUROBIOLOGIST

The Department of Neurobiology is seeking a new faculty member at the assistant-professor level to begin in 1979 or 1980. Applications from women and minority people are encouraged. Please send curriculum vitae and a brief outline of research plans, and have three letters of reference sent to: Search Committee, Department of Neurobiology, Harvard Medical School, 25 Shattuck Street, Boston MA 02115. W99(A)

# Research Officer

## Chemistry Section

NIBSC is an Institute concerned with the standardisation and control of biological substances used in medicine and is a WHO laboratory for biological standards. The work of the Institute is well supported by research.

Applications are invited for a Research Officer in the Chemistry Section. The post is in the laboratory concerned with polysaccharides and the application of methods of carbohydrate chemistry to analyse other substances such as antibiotics. Applicants should have or expect to gain this year a first degree in an appropriate subject.

**Salary, depending upon age and experience, on the scale £3,715—£5,259 p.a. (under review), including London Weighting, plus superannuation benefits.**

Please write or telephone for further details and an application form, quoting reference CH/161, to the Personnel Officer, NIBSC, Holly Hill, Hampstead, London NW3 6RB (Tel: 01-435 2232, ext. 200).

**NIBSC**

National Institute for Biological Standards and Control

ROYAL HOSPITAL for Sick Children and Queen Mother's Hospital, Glasgow G3 8SJ. Assistant Cytogenetic science graduate, required for West of Scotland Genetic Advisory Service, to work on the diagnosis of human chromosome aberrations and other disorders. Experience in cytogenetics and cell culture desirable but not essential. Further details may be obtained from the University Department of Medical Genetics (041-339-888; Ext. 7117). Applications, with full details of qualifications and experience and names of two referees, to Personnel Office, Royal Hospital for Sick Children, Yorkhill, Glasgow G3 8SJ 738(A)

# LOTHIAN HEALTH BOARD BASIC GRADE CYTOGENETICIST

Applications are invited from science graduates for the above post based at the Department of Pathology, Royal Hospital for Sick Children, Edinburgh. Experience in human cytogenetics desirable.

All types of cytogenetic investigation are undertaken including the pre-natal diagnosis of chromosome disorders, blood culture analysis, bone marrow investigation and the karyotyping of post-mortem and spontaneous abortion material. A broad training in cytogenetics would be afforded.

Arrangements to visit the department may be made by telephoning 331-667 1991, ext. 270.

Salary scale: £2,991 to £4,899 per annum with placement according to qualifications and experience.

Applications, which should be type-written, giving particulars of age, qualifications and previous experience, together with the names, addresses and telephone numbers of two referees should be lodged with the Secretary, 11 Drumshugh Gardens, Edinburgh EH3 7QQ by May 24, 1979. 686(A)

# THE UNIVERSITY OF MANCHESTER DEPARTMENT OF PHARMACY EXPERIMENTAL OFFICER

The person appointed will be responsible for the development and co-ordination of bioanalytical techniques in research dealing with drug metabolism and disposition. The techniques primarily involve the use of chromatography, spectroscopy and radioactivity. Applicants must be graduates in either chemistry, biochemistry, or a related science, with a minimum of two years relevant experience post degree. Initial salary in the range £3,384 to £5,604 per annum (under review), superannuation under U.S.S. Particulars and application forms (returnable by June 15) from the Registrar, The University, Manchester M13 9PL. Quote ref: 96/79/N. 692(A)

# ROYAL FREE HOSPITAL SCHOOL OF MEDICINE

(University of London)

DEPARTMENT OF  
PHARMACOLOGY

Applications are invited from

POSTDOCTORAL  
BIOCHEMISTS

For the post of Lecturer in Biochemical Pharmacology in the Department of Pharmacology, which is now housed in the Clinical Sciences Building, Royal Free Hospital, Hampstead. Some experience in muscle biochemistry desirable. Salary scale (under review) at present £3,909 to £7,754 plus £502 London Allowance and superannuation benefits. Applications (six copies) should be sent by June 1, 1979 to the Secretary, R.F.H.S.M., 8 Hunter Street, London WC1N 1BP, from whom further particulars may be obtained. 690(A)

# UNIVERSITY OF LIVERPOOL

DEPARTMENT OF ZOOLOGY

Applications are invited for the post of

SENIOR

RESEARCH ASSISTANT

in the Department of Zoology.

The project is on the adaptation of ion transport in erythrocytes of salinity-acclimated trout and involves isotope flux and cell culture techniques.

Initial salary £3,883, £4,133 or £4,382 per annum (under review).

Applications, together with the names of two referees, should be received not later than May 31, 1979, by The Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref. RV/584/N. 689(A)

# OVERSEAS DEVELOPMENT

KNOW-HOW: vital to developing countries

# Nutritionist

Bangladesh

Wanted for attachment to the Ministry of Relief and Rehabilitation to assist in the organisation and evaluation of various feeding schemes including a Food for Work programme and in association with a World Food Programme designed to mitigate the severity of malnutrition among mothers and children. Applicants should have a postgraduate qualification in nutrition and post qualification experience in a developing country.

Appointment 3 years. Salary (UK taxable) according to age and experience plus a variable tax free allowance currently in range £1,030—£2,640 according to marital status.

*The post is wholly financed by the British Government under Britain's programme of aid to the developing countries. In addition to basic salary and overseas allowances other benefits normally include paid leave, free family passages, children's education allowances and holiday visits, free accommodation and medical attention. Applicants should be citizens of the United Kingdom.*

*For full details and application form please apply, quoting ref. 319x stating post concerned, and giving details of age, qualifications and experience to:—*

Appointments Officer,  
MINISTRY OF OVERSEAS DEVELOPMENT,  
Room 301, Eland House,  
Stag Place, London SW1E 5DH.

**HELPING NATIONS HELP THEMSELVES**

# UNIVERSITY OF LEICESTER DEPARTMENT OF ANATOMY RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant on an M.R.C. funded project involving physiological and anatomical studies of the mammalian carotid body. The position is tenable for three years in the first instance and the salary will be on the grade 1B scale.

Interested persons should write to Dr D. J. Pallot, Department of Anatomy, University of Leicester, University Road, Leicester LE1 7RH, giving full personal details and the names of two referees. 733(A)

**INSTITUTE OF CANCER Research:** There is a vacancy for a TECHNICIAN to work in the Radiotherapy Research Laboratories at Sutton in a research programme on in vitro tests for the sensitivity of human tumour cells to cancer chemotherapeutic agents. The work involves specialised tissue culture techniques as well as some laboratory animal work with xenografted human tumours. Experience in pharmacology would be an advantage. The appointment will be on the Technician scale which starts at £3,261 per annum plus London Allowance of £354 per annum. Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref. 301/B/62. 735(A)

# LEICESTER UNIVERSITY

# F. W. BENNETT CHAIR OF GEOLOGY

Applications are invited for the F. W. Bennett Chair of Geology formerly held by the late Professor P. C. Sylvester-Bradley. There is no restriction as to the special interests of applicants.

Further particulars from the Registrar to whom applications should be sent by June 15, 1979. Candidates in the U.K. should submit fifteen copies of their application (overseas candidates may submit one copy). 669(A)

LAMBETH is one of the foremost authorities in the country in the provision of comprehensive Environmental Health and Consumer Services. It has achieved this position through a combination of far sighted policies, adequate resources and highly qualified staff. The following vacancies now exist:

## RESEARCH OFFICERS(4)

Ref E34

Salary: £5,208 - £5,508 p.a. incl.

### Postdoctoral Research at the sharp end

Applicants should have a good record of academic achievement in preferably one or more of the following subject areas: Environmental Sciences; Political/Social Studies; Statistics; Economics; Marketing; Operational Research; Law.

The Directorate employs over 400 staff who are primarily engaged in providing operational services to the public. As a consequence, the Research facility is fundamental to policy and developments within the fields of Consumer Protection and Environmental Health. These posts offer an excellent opportunity for people with proven research capabilities to relate their skills to services designed to tackle the community's economic and environmental problems.

## INFORMATION AND PLANNING OFFICER

Ref E33

Salary: £4,680 - £6,003

The Directorate has just completed a major review of its support and administrative organisation. Now we are seeking an experienced analyst to spearhead the development of our management information and administrative systems in conjunction with the progressive application of word-processing, micro-filming and computerisation. In addition the Information and Planning Officer will contribute to the systems aspects of Committee Continuity, report preparation and corporate management particularly in respect of devising processes for target setting and effectiveness monitoring. The postholder should be able to familiarise him or herself with how the professional officers serve the public as well as meeting support requirements of senior management. You should be well qualified, both academically and professionally and we are interested in someone with a record of practical relevant achievements. A local government background is not essential.

If you would like an application form please contact the Personnel Section, Directorate of Environmental Health & Consumer Services, London Borough of Lambeth, Blue Star House, 234/244 Stockwell Road, London SW9 9SR. Tel: 01-274 7722 ext. 239. Closing date for completed applications 1st June 1979. These posts are open to both sexes and all races.

728(A)

# LAMBETH

## Senior Clinical Research Associate Guildford

Berk Pharmaceuticals, part of a major International Health Care Group, is engaged in the manufacture, marketing and distribution of a wide range of ethical drugs and is situated in a pleasant rural part of Surrey. Due to the continued expansion of our Medical Division we require a Senior C.R.A. who will play an important integral role in our clinical trials programme. You will take part in the research of compounds through phases 1, 2 and 3 of their development by designing protocols, actively participating in clinical studies and the assessment and presentation of results.

We are looking for either, someone who has a Ph.D. in the sciences or is working towards such a qualification, or a Senior Nurse with sound experience of Clinical Investigation work. Some knowledge of computing relating to the verification and processing of trial data would be an advantage but is not essential.

In addition to a competitive salary we offer 4 weeks annual leave, productivity bonus, pension scheme and other benefits.

If you are interested please telephone or write for an application form or send full C.V. to:—

Alan Ford, Personnel Department,  
Berk Pharmaceuticals Limited,  
Station Road, Shalford,  
Guildford, Surrey GU4 8HE.  
Tel: Guildford 71221 ext. 230.

720(A)

### UNIVERSITY OF NOTTINGHAM DEPARTMENT OF BOTANY

It is likely that one postgraduate research studentship will be available for work in one of the following areas:

- (1) Endocytosis and intracellular digestion in the ciliate *Tetrahymena*.
- (2) The cell cycle in green algae.
- (3) Nitrogen metabolism in *Rhodospirillum rubrum*.

- (4) Cytological studies on ferns.
- (5) Localisation of metabolic sites of action of herbicides in isolated mesophyll tissue.

- (6) Causal factors and physiological function of swollen lateral roots in the *Cyperaceae*.

- (7) Quantitative studies on plant cell ultrastructure.

If you are interested in research in one of these areas will you please write as soon as possible to Professor E. C. Cocking, Department of Botany, University of Nottingham, University Park, Nottingham NG7 2RD, indicating which area is of interest, giving a curriculum vitae and the names and addresses of two referees.

758(F)

### POSTDOCTORAL POSITION AVAILABLE

A postdoctoral position will be available in July, 1979 for appointees having either a Ph.D. in biochemistry or microbiology. Experience in enzymology desirable, though not critical. The project will be concerned with the regulation of carbohydrate metabolism during development in the slime mold, *Dictyostelium discoideum*.

Please send curriculum vitae and three references to Dr K. A. Killick, Boston Biomedical Research Institute, Department of Developmental Biology, 20 Staniford Street, Boston, Mass. 02114, U.S.A.

We are an "Equal Opportunity/Affirmative Action Employer."

W111(A)

### NATURE CONSERVANCY COUNCIL CHIEF WARDEN

Salary Range £4,809 to £5,475 (under review)

Applications are invited for the post of CHIEF WARDEN—SOUTH WALES, based in the N.C.C. Regional Office at Cardiff.

The successful applicant will be responsible to the Regional Officer for all management work in the National Nature Reserves in the South Wales Region. Duties will include the direction and supervision of the work of the two Reserve Wardens, of Estate Worker, and the temporary and Voluntary Wardens on Reserves, and the development and extension of the voluntary wardens system in the South Wales Region.

The Chief Warden will also be responsible for the formulation and forward working programmes, estimating and controlling the financial allocations for all estate work, advising on and implementing matters concerning the health and safety of staff and visitors on reserves, advising land owners and managers on land management matters, and contributing to and participating in the educational interpretative, survey and monitoring programmes of the Region.

Candidates should be over 26 years of age on June 15, 1979, physically fit and have a full current driving licence.

Further particulars and an application form can be obtained from:

The Nature Conservancy Council  
Recruitment Section  
P.O. Box 6  
George Street  
Huntingdon  
Cambs.

Tel. 0480 (Huntingdon) 56191  
Closing date for receipt of completed applications: June 1, 1979.

717(A)

# BEATSON INSTITUTE FOR CANCER RESEARCH SCIENTIST

(Geneticist or Biochemist)

There will be a vacancy from October 1, 1979 for a postdoctoral research scientist to join a team investigating the regulation of transcription of the globin genes in mammals. The work involves genetic manipulation, including the cloning of human genes, and previous experience in handling bacteriophage and/or nucleic acid enzymology is desirable. The Beatson Institute has category 2 and category 3 containment facilities and a core of staff with experience in genetic engineering. Several other projects using this technology are being pursued concurrently.

The appointment will be for three years in the first instance and will be at the appropriate point on the University of Glasgow's Research Assistant scales (which correspond to M.R.C. scales). M.R.C. terms of service apply. Applications should include a C.V. and names of referees. Address enquiries to:—

The Director,  
Beatson Institute for Cancer  
Research,  
Garscube Estate,  
Switchback Road,  
Beardsden,  
Glasgow G61 1BD.

726(A)

# NMR POSTDOCTORAL POSITION

Applications are invited for post-doctoral work on the NMR of systems of chemical and biological interest, under the direction of Professors H. S. Gutowsky and Eric Oldfield. Fourier transform spectrometers equipped with widebore superconducting magnets, operating at 360, 220 and 150 MHz, are available for use on the following projects: (1) Deuterium NMR of specifically  $^2\text{H}$ -labelled membranes. (2) Phosphorus-31 NMR studies of protein-lipid interaction in model and biological membrane systems. (3) High-resolution  $^{13}\text{C}$  NMR spectra of proteins in solution and in the crystalline solid state. (4) NMR studies of metal ion nuclei in solution and in the solid-state, with special emphasis on systems of biological importance (such as  $^{57}\text{Fe}$ ,  $^{23}\text{Na}$ ,  $^{39}\text{K}$ ,  $^{67}\text{Zn}$ ). Applications consisting of a curriculum vitae, list of publications and letters from three referees should be sent to: Professor H. S. Gutowsky, School of Chemical Sciences, University of Illinois at Urbana, Urbana, Illinois 61801, U.S.A. The University of Illinois is an Equal Opportunity/Affirmative Action Employer.

W110(A)

# UNIVERSITY OF SOUTHAMPTON

## MEDICAL ONCOLOGY UNIT

Applications are invited for the position of Postdoctoral Research Fellow in the above Unit. The person appointed will work on the isolation of cytoskeletal proteins and their interaction with the cell surface, in close cooperation with a group interested in cell adhesion and with others interested in clinical aspects of cancer research. Applicants should either be about to obtain or have recently obtained a Ph.D. in Biochemistry or some related discipline. Experience of protein biochemistry, membrane biochemistry or immunology would be advantageous. The appointment will be for one year in the first instance, renewable annually for at least three years.

Salary Range: £3,883 to £4,822 per annum (under review). U.S.S. benefits.

Applications giving date of birth, curriculum vitae and the names and addresses of two referees, should be sent to Mrs P. Vaughan-Smith, The University, Southampton SO9 5NH, not later than May 18, 1979. Please quote reference 1069/R/N.

598(A)

# LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

(University of London)

Keppel Street WC1 7HT

## DEPARTMENT OF MEDICAL MICROBIOLOGY A HISTOLOGY MEDICAL LABORATORY SCIENTIFIC OFFICER

is required to work for up to one year on histological research in immunopathology, hepatitis and mycotic infections: experience in histological techniques is essential. In addition, candidates should hold H.N.C./H.N.D./degree in a relevant subject. Salary is in the range £3,261 to £3,930 plus £354 London Weighting. Applications, consisting of full education and career details and naming two referees, should be sent to Secretary (A1) at the School.

742(A)

## DEPARTMENT OF PHYSICS UNIVERSITY OF CAMBRIDGE A RESEARCH ASSOCIATE

is required in the Cavendish Laboratory to assist with the development of scientific instrumentation used in Solid State and Surface Physics research and to be responsible for maintaining U.H.V. and computer-controlled electron-optical and cryogenics apparatus.

Experience and a high level of expertise in U.H.V. engineering design and in electronics is desirable. A degree or equivalent qualification is preferred although proven abilities in the above techniques are the prime consideration. The appointment is sponsored by the Royal Society for two years from September 1979 and there is a possibility of a tenured University post thereafter. Salary on a scale to £6,080 p.a. (under review) according to age and experience. Three copies of applications including a full c.v. and names of referees should be sent to Mr. J. Deakin, Secretary of the Department of Physics, Cavendish Laboratory, Madingley Road, Cambridge CB3 0HE before May 31.

710(A)

## THE UNIVERSITY OF MANCHESTER RESEARCH TECHNICIAN (GRADE 3)

### DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY, WITHINGTON HOSPITAL

Required to assist in the measurement of steroid hormone receptors in the female genital tract. Candidates should possess at least O.N.C. or equivalent and have experience in the measurement of steroid hormone receptors.

Suitable candidates may be considered for registration for higher qualifications.

Salary scale £2,931 to £3,336 per annum.

Applications including a curriculum vitae and the name and address of two referees (as to technical or academic ability) should be sent as soon as possible to Mrs B. Steele, Department of Obstetrics and Gynaecology, Research and Teaching Building, University Hospital of South Manchester, West Didsbury, Manchester M20 8LR not later than May 25, 1979.

732(A)

# CSIRO

# AUSTRALIA

## Assistant Chief Division of Animal Production Tropical Cattle Research Centre Rockhampton, Queensland

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees—2,400 of whom are research and professional scientists—located in Division and Sections throughout Australia.

**General:** Research in the Division of Animal Production is concerned with the solution of major problems in the animal industries, and in the provision of new and improved technologies that result in substantial gains in the efficiency of livestock production.

The Division has six broadly-based research programmes each of which is co-ordinated by a Programme Chairman. These programmes include work on nutrition, reproduction, genetics and animal breeding, skin and fleece biology, mineral requirements, and tropical animal production.

Current research at Rockhampton involves the genetic improvement of productivity in beef cattle for Northern Australia. Research is being expanded to complement this objective by developing new research initiatives in the fields of reproduction, nutrition and environmental adaptation.

### Duties:

1. To assist the Chief and to advise Programme Chairmen in the planning and development of research priorities directed towards the efficiency of livestock production in tropical and sub-tropical areas of Northern Australia. The research will, in the main, be directed towards studies on both the genetic and environmental factors which influence productivity. The Assistant Chief will initially be required to act as Programme Chairman of the Tropical Animal Production Programme.

2. To be responsible for the administration of the Rockhampton facilities which will include a major laboratory complex due for completion in 1980.

**Qualifications:** Applicants should have a substantial record of research achievement and an appreciation of problems in animal production in tropical and sub-tropical areas. In particular, applicants should have an established reputation of outstanding achievement in some field of animal production, e.g. genetics, environmental adaptation, nutrition of reproduction.

**Salary:** Senior Principal Research Scientist \$27,790 to \$30,530 p.a. or Chief Research Scientist Grade I \$31,407 p.a.

**Tenure:** This is an indefinite appointment which carries superannuation benefits subject to normal conditions. However, the role of Assistant Chief is offered for a term of three years. The situation will then be reviewed to determine whether the appointee should continue as Assistant Chief for a further period or as a senior research worker.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 245/721 should reach:

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 9th June 1979.

Applications in U.S.A. and Canada should be sent to: The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A.

756(A)

## UNIVERSITY OF EXETER DEPARTMENT OF GEOGRAPHY RESEARCH ASSISTANT

Applications are invited for a graduate research assistant to work with Dr E. Maltby in an investigation of differential trends in upland soil development resulting from reclamation of moorland for agriculture. Familiarity with techniques of chemical and physical analysis of soils and their description in the field would be an advantage.

The post which is supported by an N.E.R.C. research grant is tenable for two years from November 1, 1979. The initial salary is £3,384 plus U.S.S.

Applications and requests for further details should be addressed to Dr E. Maltby, Department of Geography, University of Exeter, Amory Building, Rennes Drive, Exeter EX4 4RJ as soon as possible.

684(A)

## OXFORD POLYTECHNIC DEPARTMENT OF BIOLOGY

### SENIOR LECTURER or LECTURER II IN PLANT PHYSIOLOGY

Applications are invited from suitably qualified candidates to take part in teaching and research in plant physiology as well as in the general teaching of ecology at honours degree and higher technician levels.

Salaries: Senior Lecturer £6,051 to £7,065 (bar) to £7,572. Lecturer II £4,101 to £6,558. Under review from April 1, 1979 (transfer from Lecturer II to Senior Lecturer is, subject to efficiency requirements, automatic).

Applications, including a curriculum vitae and the names of three referees, should be sent as soon as possible to the Head of Department of Biology, Oxford Polytechnic, Oxford OX3 0BP, from whom further particulars and application forms may be obtained.

722(A)

Centre for Applied Microbiology & Research,  
Porton Down, Salisbury, Wiltshire

## The Vaccine Research and Production Laboratory

has the following vacancies for suitably qualified scientists.

### 1. Vaccine Development

**A Microbiologist/Microbial Biochemist** to work in a small group concerned with the development of bacterial vaccines. The work will involve identification and separation of immunogenic components and production of trial batches for evaluation. Preference will be given to candidates who have up-to-date experience in microbial biochemistry and separation techniques.

### 2. Vaccine Assessment

**A Microbial Biochemist** to take a leading role in developing a programme concerned with methods for the assessment of potency and safety with particular reference to subunit vaccines. Preference will be given to candidates who have experience in immunology, biochemistry or pathogenicity.

### 3. Vaccine Production

**A Chief or Senior Medical Laboratory Scientific Officer** to participate in the development of a capability for vaccinia virus production, including quality control, storage and distribution of the vaccine. Research in viral vaccine development will be encouraged. Preference will be given to candidates with experience in virology and animal handling.

### 4. Vaccine Production

**A Medical Laboratory Scientific Officer** principally to supervise the tissue cell production unit but also to participate in the development of a vaccinia virus production capability. Preference will be given to candidates with experience in tissue culture and virology or animal handling.

Appointment for Posts 1 and 2 may be at either Senior Grade (£5,451 to £6,837) or Basic Grade Microbiologist (£2,991 to £4,899) depending upon qualifications and experience. A good honours degree or equivalent is essential and for a Senior Grade position a record of proven research ability.

Salaries on the Medical Laboratory Scientific Officer scale are: Chief (£5,472 to £6,192), Senior (£4,347 to £5,769), Basic Grade (£3,261 to £4,680), the assimilation point will depend upon qualifications and experience.

Further details of the posts can be obtained from Dr J. Melling, Director, Vaccine Research & Production Laboratory. (Tel. (0980) 610391).

*Applications stating date of birth, qualifications, experience and publications and naming three referees should be sent to Mrs M. Bushby, C.A.M.R., Porton Down, Salisbury, Wilts SP4 0JG by June 1, 1979.*

#### UNIVERSITY COLLEGE DUBLIN PROFESSORSHIP OF GEOLOGY

The closing date for applications for the above appointment has been extended to **Thursday, May 31, 1979.**

Applicants who have not received acknowledgement of their applications and prospective applicants should telephone University College Dublin 693244, extensions 658, 657 or 416. 743(A)

#### ST HELIER HOSPITAL WRYTHE LANE CARSHALTON, SURREY SCIENTIFIC ASSISTANT

##### DERMATOLOGY DEPARTMENT

With postgraduate experience in either Biochemistry or Immunology to work on skin diseases including malignancy.

Apply to June 30 to Dr E. L. Rhodes at the above address. 759(A)

#### DIRECTOR DALTON RESEARCH CENTER UNIVERSITY OF MISSOURI COLUMBIA (Continuing Search)

This multidisciplinary facility for basic biological research, graduate and postgraduate training is supported principally from state funds, as well as from Federal agencies and foundations. A new building of 60,000 sq. ft. in Research Park, adjacent to the main campus, has excellent research laboratories with modern animal shop, computer, controlled environment, and other facilities.

A Director is sought with commitment to outstanding research who will develop a dynamic research unit in a life science area. The Director will be expected to bridge and complement Dalton Center activities with selected existing talents and resources on the UMC campus; examples are cardiovascular regulation, cellular and developmental biology, molecular genetics, immunobiology, neurosciences, and bioengineering.

This is intended as a "Center of Excellence" and the University is committed to providing a competitive Director's salary and other resources to insure success. The Director should have research management experience, including budgeting, recruiting, and generating research funds.

The Director will be tenured in an academic department of UMC. The University is a Land Grant school with a student enrolment of 23,000. On a single campus, it has a unique combination of life science-oriented Divisions (Medicine and other health related sciences, Agriculture, Veterinary Medicine, Engineering, and Biological Sciences). Particular research strengths may be found in departments of Biochemistry, Physiology, Biological Sciences, Bioengineering, Medicine, Microbiology, Pharmacology, Radiology, and Surgery. University resources include Reactor Research Center, Cancer Research Center, Health Services Research Center, Veterans Administration Hospital, University of Missouri Medical Center, and Eye Research Institute.

Women and members of minority groups are urged to apply. Resumes and other appropriate information should be sent to:

Search Committee for Director  
Dalton Research Center  
Research Park  
University of Missouri  
Columbia, Missouri 65211  
The University of Missouri is  
an Equal Opportunity Employer.

#### UNIVERSITY OF LIVERPOOL DEPARTMENT OF BOTANY RESEARCH ASSISTANT

Applications are invited for the post of Research Assistant to assist in studies of numerical taxonomy and phage typing of streptomycetes (actinomycetes), in a joint research programme with the Department of Microbiology, University of Newcastle upon Tyne supported by S.R.C. Applicants should have or expect to obtain a degree in a biological science with experience in microbiology.

The Research Programme will last for one year starting in August 1979, and the salary is £3,384 per annum.

Applications, together with the names of two referees, should be received not later than May 25, 1979, by The Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref. RV/588/N. 697(A)

#### NATURE CONSERVANCY COUNCIL

SEABIRDS AT  
SEA RESEARCH  
SENIOR SCIENTIFIC  
OFFICER (1) AND HIGH  
SCIENTIFIC OFFICER (2)  
(3 year posts)

STARTING SALARY (at pre under review)

HIGHER SCIENTIFIC OFFICER

£4,101

SENIOR SCIENTIFIC OFFICER

£5,154

Salary on appointment may be in excess of these figures, depending on experience and qualification. Applications are invited for following four contract posts in Nature Conservancy Council's "birds at sea" Research Team. Posts are for a fixed period of 4 years only.

#### BACKGROUND

The seabirds at sea research programme is designed to investigate behaviour and distribution of seabirds offshore. Effort will be concentrated primarily in the North Sea and results will be used to refine N.C. response in relation to oil spill contingency planning.

#### THE POSTS

(a) **ORNITHOLOGIST** (Three posts) A sound knowledge of ornithology is required. A special interest in experience in seabird ecology desirable.

(b) **MARINE BIOLOGIST/OCEANOGRAPHER** (One post) A sound knowledge of marine biology/oceanography is required. A special interest in fish biology and some ornithological interests are desirable.

Experience in data handling will be an asset for both posts (a) and (b). One of the posts will be designated as team leader and will be graded S.S.O. The other members of team will be graded H.S.O.

The posts are based in Aberdeen. Candidates will be required to work offshore from boats or oil exploitation structures and carry out aerial surveys using light aircraft. The posts entail a good deal of travel and time away from base. A current driving licence is essential.

#### AGE AND QUALIFICATIONS

Candidates should have a first second class honours degree equivalent in a relevant scientific subject.

**HIGHER SCIENTIFIC OFFICER** Candidates should normally be under 30 years of age and have at least 3 years' relevant post-graduate experience.

**SENIOR SCIENTIFIC OFFICER** Candidates should normally be at least 25 and under 32 years of age and have at least four years' relevant post-graduate experience.

Application forms and further details are available from Miss Bull, Recruitment Section, Nature Conservancy Council, Godwin House, George Street, Huntingdon, Cambridgeshire PE18 6BU (Tel: 0480-56191, Ext. 2). Closing date for completed applications is June 1, 1979. 718(A)

#### TECHNICIAN/RESEARCH OFFICER

required in Tumour Immunology Unit at University College, WC, for a project investigating the role of macrophages in animal human immune systems. Work will involve a great deal of tissue culture, some animal work and other immunological techniques. H.N.C./degree essential.

Salary £3,615 to £5,256. For further information and application form write or telephone Miss S. M. Hurley at the Imperial Cancer Research Fund, Lincoln Inn Fields, London WC2 on 24 0200, ext. 305. 702(A)

**ASSISTANT PROFESSOR  
OF BIOCHEMISTRY  
LSU MEDICAL CENTER  
New Orleans, Louisiana**

The Department of Biochemistry, Louisiana State University Medical Centre, invites applications for 12 months tenure-track faculty positions. Candidates should have a strong background in biochemistry or molecular biology. In addition to the School of Graduate Studies, the Medical Center includes the Medical, Dental and Nursing Schools and the School of Allied Health Professions. Applicants should have postdoctoral experience and exhibit potential for developing a strong independent research program. Interest and excellence in teaching is also expected. Applicants should send a curriculum vitae, bibliography, a short summary of research goals, and have three letters of evaluation submitted to the following: Robert Roskoski, Jr., Head, Department of Biochemistry-LSU Medical Center—1542 Tulane Avenue, New Orleans, Louisiana 70112.

The Louisiana State University is an Affirmative Action/Equal Opportunity Employer. W108(A)

SHEFFIELD  
LABORATORY  
SUPERINTENDENT  
(GRADE 8C)**

required for the Department of Geology from September 1, 1979, to be responsible for the operation of a complete technical service for teaching and research in an enlarged and modernised department. Candidates must have proven organising ability and considerable experience of science laboratories. Salary on scale £5,172 to £5,625 per annum (under review).

Please write to the Administrative Officer (Personnel), (Ref. S 1256/N), The University, Sheffield S10 2TN. 745(A)

**DEPARTMENT OF  
BIOPHYSICS  
King's College London  
POSTDOCTORAL  
RESEARCH ASSISTANT**

Postdoctoral position supported by the M.R.C. is available from June 1, 1979, to collaborate with Dr H. J. Gould on the molecular cloning and analysis of human immunoglobulin genes.

Starting date not later than September 1, 1979. Salary £3,883 to £6,555 p.a. plus London weighting.

Applications, with curriculum vitae and names of two referees, should be sent to Dr H. J. Gould, Department of Biophysics, King's College, 26-29 Drury Lane, London WC2B 5RL. 626(A)

**UNIVERSITY OF  
CAMBRIDGE  
DEPARTMENT OF GENETICS  
POSTDOCTORAL  
VIROLOGIST**

A position is available, from October 1, 1979, for 3 years, on a research project funded by the Science Research Council, for a postdoctoral virologist, preferably with experience in the molecular biology of viruses. Salary at age 27, £4,631, under review. Further details may be obtained from Dr M. Ashburner to whom applications, with the names of two referees, should be sent to reach him by June 30, 1979. Department of Genetics, Downing Street, Cambridge CB2 3EH. 707(A)

**PLANT MOLECULAR  
BIOLOGIST  
ZOECON CORPORATION**

Zoecon Corporation, a leader in innovative agricultural chemical research, is establishing a major research effort in higher plant molecular biology. Research directions will include the application of the techniques of molecular biology to crop improvement. Qualified scientists will join a research team working in a unique scientific environment. Zoecon offers an opportunity to develop and direct a research program, the intellectual stimulation of interaction with excellent colleagues, and the opportunity to contribute to the expansion of this exciting field. Individuals with expertise in plant genetics, biochemistry and physiology are encouraged to apply. The positions require a Ph.D. in a field of plant biology, preferably with post doc experience.

Zoecon is a division of Occidental Petroleum Corporation with substantial domestic and international operations. Corporate headquarters and corporate research are located in the Stanford Industrial Park, in close proximity to San Francisco. Submit detailed résumés in confidence to:

Kathy Moore  
Manager, Employee Relations  
Zoecon Corporation  
975 California Avenue  
Palo Alto, California 94304.  
W89(A)

**UNIVERSITY OF OXFORD  
POSTDOCTORAL  
RESEARCH ASSISTANT  
AND TECHNICIAN**

required for research into the regulation of branched chain 2-oxo acid dehydrogenase complex, branched chain amino acid catabolism and into disorders of branched-chain amino acid metabolism. The posts are for three years from a mutually convenient date in 1979 and are funded by the Medical Research Council. The postdoctoral research assistant should have experience in enzymology and protein chemistry and possess or expect a Ph.D. or equivalent degree. The technician should have a degree in biochemistry (or a related subject) or possess suitable laboratory experience. Starting salaries up to £4,382 (research assistant) and £3,930 (technician) on scales in operation on March 1, 1979.

Applications including the names of two referees to Professor P. J. Randle, Department of Clinical Biochemistry, Radcliffe Infirmary, Oxford OX2 6HE from whom further details may be obtained. 659(A)

**CHARING CROSS HOSPITAL  
MEDICAL SCHOOL  
(University of London)  
DEPARTMENT OF  
HAEMATOLOGY**

Non-clinical Lecturer required. Work of the appointee will be particularly concerned with surface membrane markers on lymphocytic and leukaemic cells, evaluation of immune complexes and assessment of immunoglobulin fractions. In addition the appointee will be encouraged to develop work on sub-cellular fractions. Teaching of immunology related to Haematology will be required. Post would suit a postdoctoral Fellow or equivalent.

Informal enquiries can be made to Professor G. D. Pegrum, Department of Haematology (01-748 2040, ext. 2703).

Salary on scale £3,883 to £7,754 (under review) per annum plus £502 London Weighting Allowance.

Applications, including the names and addresses of two referees, should be submitted to the School Secretary, Charing Cross Hospital Medical School, The Reynolds Building, St Dunstan's Road, London W6 8RP, by June 2, 1979. (Ref: 499/500.) 731(A)

**British Museum (Natural History),  
London.**

# Head of Freshwater Algae Section

The British Museum (Natural History) is an institution for taxonomic research and an educational focal point for the public. The main aim of the research is to produce definitive accounts of the world's animals, plants and minerals as well as the preservation of an extensive collection of fossils.

The successful candidate will supervise the work of junior staff, conduct research on the taxonomy of freshwater Chlorophyta and/or Rhodophyta and organise the Section's curatorial and advisory services.

Candidates, normally aged under 32, should have a good honours degree or equivalent in an appropriate discipline and at least two years' postgraduate experience. Experience in algal taxonomy is highly desirable.

Appointment as Senior Scientific Officer (£5,675 to £7,420) or Higher Scientific Officer (£4,620 to £5,970) according to qualifications and experience. *Salaries under review.* Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by June 6, 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants. RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). *Please quote ref: SB/55/DK.*

# Science Group CIVIL SERVICE

# CHAIRMAN DEPARTMENT OF MEDICINE

**THE UNIVERSITY OF CHICAGO  
PRITZKER SCHOOL OF MEDICINE**

Applications are invited for the position of Chairman of the Department of Medicine, The University of Chicago—Pritzker School of Medicine. Send letters of application and supporting information to:

**JARL E. DYRUD, M.D.,  
Associate Dean for Faculty**

**THE UNIVERSITY OF CHICAGO  
PRITZKER SCHOOL OF MEDICINE**

**950 E. 59th Street, Box 411  
Chicago, Illinois 60637**

An Affirmative Action/Equal Opportunity Employer

W112(A)

## UNIVERSITY OF NOTTINGHAM ENVIRONMENTAL PHYSICS AND PHYSIOLOGY

Applications are invited from graduates and post-graduates for posts tenable for three years on the following interdisciplinary projects supported by the Department of the Environment and the Natural Environment Research Council.

### RESPONSES OF WHEAT TO SULPHUR DIOXIDE (two posts)

Graduate research assistant—to develop a computer-controlled system for exposing areas of field crops to air pollution and to investigate turbulent fluctuations in pollutant concentrations. A suitably qualified applicant may register for a higher degree.

Postdoctoral research fellow—to study growth, development and yield of wheat in response to sulphur dioxide. Applicants should have a doctorate in an appropriate branch of biological science.

### FOG CAPTURE BY VEGETATION—A PATHWAY FOR POLLUTANT DEPOSITION

Postdoctoral research fellow—to measure fluxes of fog to a forest and to isolated trees and shrubs and to determine pollutant concentrations in the fog droplets. Part of the field work will be Northern England and Central Scotland. Applicants should preferably have a doctorate in physics, meteorology or related branches of physical science.

### THE HEAT BALANCE OF WET VEGETATION

Ph.D. Research studentship—to make micrometeorological studies of factors determining the duration of leaf wetness and to develop computer simulation models. A good honours degree in physics or environmental science is desirable.

#### Salaries

Postdoctoral fellow: on the scale £4,333 to £4,910.

Graduate assistant: on the scale £3,775 to £4,333.

Research student: Research Council rates plus fees and allowances.

For further details of all projects write to Dr M. H. Unsworth, Department of Physiology and Environmental Studies, University of Nottingham School of Agriculture, Sutton Bonington, Loughborough LE12 5RD. 693(A)

## DIRECTOR INSTITUTE OF MARINE SCIENCE UNIVERSITY OF ALASKA

The University of Alaska, Fairbanks, invites applications for the position of Director, Institute of Marine Science and Division of Marine Sciences. Qualifications sought are a doctoral degree, leadership in interdisciplinary research management, experience in dealing with funding sources, and a knowledge of budgetary operations. A distinguished research record is expected. Experience in teaching and the supervision of thesis projects of graduate students is desirable. Marine Sciences at the University have a full-time faculty of 23 and a graduate student enrolment of about 40.

Applications or nominations with biographical and other pertinent information should be received before July 1, 1977, by the chairman of the search committee:

Dr Gunter E. Weller  
Geophysical Institute  
University of Alaska  
Fairbanks, Alaska 99701 U.S.A.

The University of Alaska offers equal educational and employment opportunities. W113(A)

## FACULTY POSITIONS PARASITOLOGY

The Department of Pathobiology, University of Pennsylvania School of Veterinary Medicine is inviting applications for faculty positions in the Laboratory of Parasitology. Applicants are expected to have a D.V.M. and/or Ph.D. degree and have a demonstrated ability and interest in research and teaching in parasitology. Major research interests in the laboratory at present are in the areas of immunoparasitology and ecological parasitology. Faculty rank and salary open. Candidates are requested to send resumes and names of references to Dr W. C. Wilcox, Chairman of the Search Committee, Department of Pathobiology, School of Veterinary Medicine, University of Pennsylvania, Philadelphia, Pa. 19174.

An equal opportunity, affirmative action employer. W109(A)

## UNIVERSITY OF NEWCASTLE UPON TYNE THE ENERGY CENTRE

Postgrad. or Postdoc. from suitable discipline (Science, Engineering, Statistics, or possibly Economics or Social Sciences) with interest in energy matters, for research project on Risks of Conventional Electricity Production.

Initially one year contract; salary according to qualifications and experience.

Write, enclosing curriculum vitae, to Professor G. R. Bainbridge, Director, The Energy Centre, University of Newcastle upon Tyne, 37 Jesmond Road, Newcastle upon Tyne NE2 4EU. 709(A)

UNIVERSITY COLLEGE Hospital. Scientific Officer (two posts), Applications are invited from suitably qualified graduates to work in the Haematology Research Department on the antenatal diagnosis of thalassaemia. Salary on the scale of £3,345 to £5,253 dependent upon qualifications and experience. Further information from Professor Huehns, Clinical Haematology Department, University College Hospital, Medical School, University Street, WC1. Application forms from Personnel Department, University College Hospital, Gower Street, WC1. Closing date: 10 days after appearance of this advertisement. 737(A)

## UNIVERSITY OF LIVERPOOL DEPARTMENT OF GEOLOGY

Applications are invited for the post of

### DEMONSTRATOR/ SENIOR DEMONSTRATOR

in the Department of Geology. Applicants should have an interest in some aspect of structural geology and experience of field studies is essential. Teaching duties will be concerned mainly with structural courses.

The post is tenable from October 1, 1979, for one year in the first instance, renewable yearly though not normally more than twice.

Initial salary on the scale £3,384 to £4,882 per annum (under review).

Applications, together with the names of three referees, should be received not later than May 25, 1979, by the Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/589/N. 696(A)

## QUEENSLAND INSTITUTE OF TECHNOLOGY SENIOR LECTURER— HUMAN PHYSIOLOGY

Applications are invited from suitably qualified medical graduates for this newly established full-time tenured post. The appointee should have been involved in tertiary teaching and would be required to exercise leadership in the teaching of human physiology. The pursuit of a research interest would be encouraged and professional experience programmes are available. A generous superannuation scheme operates.

Salary will be within the range A\$21,180 to A\$24,687 per annum.

Full details of the post and the Institute are available from the Agent General for Queensland, 392 The Strand, London WC2R 0LZ or telephone (01) 836 3224.

Applications quoting V.51/79 and containing the names of three referees should reach the Personnel Officer, Q.I.T., George Street, Brisbane 4000 Australia by July 27, 1979. W103(A)

## ROTHAMSTED EXPERIMENTAL STATION HARPENDEN, HERTS. AL5 2JQ

Applications are invited from suitably qualified scientists for the post of Head of the Nematology Department which will become vacant in late 1979 on the retirement of Dr F. G. W. Jones.

The Nematology Department has about 40 scientific staff and receives many visiting workers.

The Department studies nematodes known or suspected to be plant parasites, and the research programme includes both fundamental and applied investigations. The Head of Department will be expected to encourage collaboration with other relevant disciplines at Rothamsted, and with other sections of the agricultural industry as appropriate.

Appointment in the grade of S.P.S.O., £10,043 by two increments to a maximum of £11,300 (under review). Non-contributory superannuation.

Apply in writing to the Secretary giving names and addresses of two referees and quoting Ref. 389 by June 8, 1979. Further details on request. 712(A)

RESEARCH GROUP requires laboratory scientific officer to assist genetic and cell biology work involving tissue culture. Candidates with relevant experience preferred. Applications should be sent to the Administrative Assistant, Paediatric Research Unit, The Prince Philip Research Laboratories, Guy's Hospital Medical School, London Bridge SE1 9RT. 736(A)

## ASSISTANTSHIPS

### UNIVERSITY OF DUNDEE DEPARTMENT OF CHEMISTRY

Applications are invited for a  
**POSTDOCTORAL  
RESEARCH  
ASSISTANTSHIP**

for research with Dr J. A. Miller on applications of organophosphorus chemistry to problems in organic synthetic methods and in natural product synthesis.

The preferred starting date is October 1, 1979 but earlier or later dates are negotiable. The appointment, which is financed from an S.R.C. grant is available for one year in the first instance but renewal for a second year is likely. Initial salary dependent on age, qualifications and experience but within the range £3,883 to £4,365 (under review).

Applications, with curriculum vitae and the names of two referees and quoting Ref: EST/49/79J should be sent as soon as possible (and not later than May 21, 1979) to The Secretary, The University, Dundee DD1 4HN. 706(P)

## THE QUEEN'S UNIVERSITY OF BELFAST A POSTDOCTORAL RESEARCH ASSISTANT

Department of Pure and  
Applied Physics

Applications are invited from men or women for a postdoctoral research assistantship supported by the Science Research Council in connection with an experimental study of lipid monolayers (with particular reference to their phase transitions) using laser light scattering techniques. The appointment is tenable for up to three years and initial salary will be in the range £3,885 to £4,383 (under review). Experience in computing is required; relevant experience in either lipid monolayers or photon correlation would be advantageous.

Applications with curriculum vitae and the names and addresses of two referees to the Personnel Officer, The Queen's University of Belfast BT7 INN, Northern Ireland. Closing date May 28, 1979. 687(P)

**UNIVERSITY OF CAMBRIDGE**  
Department of Botany. Postdoctoral Research Assistant. Applications are invited for a postdoctoral research assistantship to work on the biochemistry of the chloride-pump of sea avenger. The post, which is supported by the Science Research Council, is for a period of three years from October 1, 1979. The salary will be within the range 1A, starting at £3,883 to £4,382 (under review). Applications with curriculum vitae and the names and addresses of two referees should be sent as soon as possible to Dr D. E. Hanke, Botany School, Downing Street, Cambridge CB2 3EA, from whom further particulars may be obtained.

750(P)

**OXFORD UNIVERSITY**  
**INORGANIC CHEMISTRY**  
**LABORATORY**  
**POSTDOCTORAL RESEARCH**  
**ASSISTANTS: OPTICAL AND**  
**MAGNETIC PROPERTIES OF**  
**INORGANIC SOLIDS**

Applications are invited from chemists or solid-state physicists for up to three Postdoctoral Research Assistantships to work on preparation and crystal growing and on the magnetic, magneto-optical and optical properties of inorganic and metal-organic solids. Experience of either crystal growing, magnetic measurements, magneto-optics or laser spectroscopy would be an advantage. Tenable up to three years from October 1, 1979. Salary on the Science Research Council Scale 1A (£3,883 to £6,555) plus U.S.S. Applications should be sent to Dr P. Day or Dr R. G. Jennings, Inorganic Chemistry Laboratory, South Parks Road, Oxford OX1 3QR, from whom further details may be obtained.

744(A)

**UNIVERSITY OF OXFORD**  
**LABORATORY OF MOLECULAR**  
**BIOPHYSICS**  
**M.R.C.**  
**POSTDOCTORAL**  
**RESEARCH ASSISTANTSHIP**  
**IN BIOCHEMISTRY**

A post-doctoral position is available or a biochemist to work in collaboration with crystallographers on the relationship between the structure and function of glycogen phosphorylase *b*. The structural studies have reached a stage where it is possible to make definite proposals about mechanism. The biochemist would be involved in the design of experiments to test these proposals and in initiating his or her own programme of research on phosphorylase and related enzymes.

The appointment is for 3 years. Salary is on scale Grade 1A in the range £4,365 to £5,506, according to age. Applications with the names of two referees should be sent to Dr. N. Johnson, Laboratory of Molecular Biophysics, South Parks Road, Oxford OX1 3PS, from whom further information may be obtained. 711(P)

**STUDENTSHIPS**

**AGRICULTURAL**  
**RESEARCH COUNCIL**  
**STUDENTSHIP**

Applications are invited for a Studentship to work in the Protein Section of the Meat Research Institute.

The project is to investigate the turnover and remodelling of the connective tissues in relation to growth and development.

This will consist of radioactive incorporation studies together with autoradiography, the chemical analysis of connective tissue components and an examination of the cellular mechanisms for resorption of tissue.

The project is expected to form the basis for a Ph.D. thesis in the University of Bristol and the appointment will commence in October, 1979. Candidates should possess a First or Upper Second Class degree in Biochemistry.

Further particulars of the award and allowances together with Application Forms may be obtained from the Personnel Officer, Agricultural Research Council, Meat Research Institute, Langford, Bristol BS18 7DY.

747(F)

**UNIVERSITY OF LEICESTER**  
**DEPARTMENT OF**  
**MICROBIOLOGY,**  
**THE MEDICAL SCHOOL**  
**M.R.C. RESEARCH**  
**STUDENTSHIP**

Applications are invited from good honours graduates in a biological science and from students who expect to graduate in 1979 for an M.R.C. Research Studentship to investigate dimorphism and pathogenicity in *Candida albicans*. The work will involve biochemical analyses, electron microscopy and animal experimentation.

The studentship is tenable for three years, subject to satisfactory progress, and the successful candidate will be registered for the degree of Pr.D.

Applicants should write by May 25 to Dr F. C. Odds, Department of Microbiology, University of Leicester, Leicester LB1 7RH, enclosing a curriculum vitae and the names and addresses of two referees. 725(F)

**UNIVERSITY OF BRISTOL**  
**DEPARTMENT OF ZOOLOGY**  
Applications are invited for an  
**M.R.C.**

**RESEARCH STUDENTSHIP**

in Neurobiology to join a project with Dr Alan Roberts on central nervous mechanisms underlying swimming movements of amphibian embryos. Intracellular recording, neuroanatomy and digital computer modelling of neural networks will be involved.

Applicants should be interested in one of these approaches and have (or expect) a good degree in Science or Engineering. The post will be for three years from October 1979.

Applications should be sent to Suzy Oakes, Department of Zoology, University of Bristol, Woodland Road, Bristol BS8 1UG as soon as possible, and should include the names and addresses of two referees and a curriculum vitae. 699(F)

**UNIVERSITY OF**  
**MANCHESTER**  
**DEPARTMENT OF**  
**MEDICAL BIOPHYSICS**  
**RESEARCH STUDENTSHIP**  
**IN BIOPHYSICS**

Applications are invited from students having, or expecting, a good honours degree in science for an M.R.C. Research Studentship to undertake postgraduate research training in Biophysics, commencing October 1979. The successful candidate will be offered a choice of research projects and will be registered with the University for a higher degree.

Further details from Dr J. A. Chapman, Reader in Biophysics in the Department of Medical Biophysics, University of Manchester, Stoford Building, Manchester M13 9PT, to whom a detailed application, including names and addresses of two referees, should be sent as soon as possible. 721(F)

**THE POLYTECHNIC**  
**WOLVERHAMPTON**  
**DEPARTMENT OF**  
**BIOLOGICAL SCIENCES**  
**N.E.R.C. C.A.S.E.**  
**STUDENTSHIP**

To investigate aspects of decomposition of organic matter in soil in order to devise a standardised test to be used as an index of the effects of pesticides on decomposition.

Supervisors: Dr D. J. L. Harding and G. Ayers (Wolverhampton); Dr C. A. Edwards (Rothamsted Experimental Station, Harpenden).

Applicants should have or expect to obtain a good honours degree in biology or ecology, preferably with experience in microbiology.

The student will be registered with C.N.A.A. for M.Phil./Phd. Further details and application forms are available from "Personnel" The Polytechnic, Wolverhampton WV1 1LY. 754(F)

**THE UNIVERSITY**  
**OF MANCHESTER**  
**DEPARTMENT OF PHYSIOLOGY**  
**RESEARCH STUDENTSHIPS**

Applications are invited for three postgraduate research studentships (M.R.C. and S.R.C. tenable in the Department of Physiology from October 1, 1979. The value of the awards will be according to Research Council Scales. These awards are for research into: secretion of electrolytes and enzymes by exocrine glands; renal function in pregnancy; human circadian rhythms; cardiovascular reflexes; central neurotransmitters; cerebellar neurophysiology; physiology of dystrophic muscle. Eligible candidates should hold or expect to obtain a good Honours degree in physiology, pharmacology, biochemistry or other related subjects. Applications, together with the names and addresses of two referees should be sent as soon as possible to Dr A. C. Wareham, Department of Physiology, The Medical School, University of Manchester, Manchester M13 9PT. Telephone: 061-273-8241. 691(F)

**UNIVERSITY OF**  
**NEWCASTLE UPON TYNE**  
**DEPARTMENT OF**  
**DERMATOLOGY**

**Postgraduate Research**  
**Studentship**

Applications are invited from honours graduates, or prospective honours graduates, for a Junior Research Associateship which is available for up to three years in the Department of Dermatology for research into the action of pigmentary peptides in the skin. The research methods will include bioassay in conjunction with radioimmunoassay and chromatography. The successful candidate will be required to register for a higher degree and will be awarded maintenance allowances equivalent to those of M.R.C./S.R.C. studentships.

Applications giving a brief curriculum vitae and the names of two referees should be submitted by May 25, 1979 to Professor S. Shuster, Department of Dermatology, Royal Victoria Infirmary, Newcastle upon Tyne. 734(F)

**UNIVERSITY OF**  
**NEWCASTLE UPON TYNE**  
**Muscular Dystrophy Group**  
**Research Studentship**

Applications are invited from graduates in physiology, pharmacology, zoology or other appropriate biological sciences for a research studentship. The successful applicant will work on aspects of neuromuscular transmission in mice suffering from inherited diseases of the peripheral nervous system, and will need to adopt a multidisciplinary approach involving both physiological and morphological studies.

The studentship (value £1,610 per annum) is tenable for three years and will be held at the Muscular Dystrophy Group Laboratories, Newcastle upon Tyne.

Applicants should contact Dr J. B. HARRIS, Muscular Dystrophy Group Laboratories, Newcastle General Hospital, Westgate Road, Newcastle upon Tyne NE4 6BE for further details. Applications should consist of a curriculum vitae, a statement of academic interests and the names of two referees and should be sent directly to Dr J. B. HARRIS, at the above address by June 8, 1979. 752(F)

**UNIVERSITY OF**  
**ABERDEEN**  
**DEPARTMENT OF**  
**MICROBIOLOGY**

The Department has a number of  
**RESEARCH STUDENTSHIPS**

available from October 1979. These will be for research in the areas of:—kinetics and genetics of bacterial transport systems; microbial interactions in soil nitrification; wall synthesis and morphogenesis in pathogenic fungi; origins and function of chitinase in fish; physiology and ecology of sulphate reducing bacteria in relation to North Sea oil industry.

Enquiries and applications from suitably qualified graduates or final year students in microbiology and related disciplines, should be addressed to Head, Department of Microbiology, University of Aberdeen, Marischal College, Aberdeen AB9 1AS. 704(F)

**COURSES**

**EMBO COURSE**  
**ELECTRON MICROSCOPY**  
**OF NUCLEIC ACIDS**

An advanced practical course on electron microscopy of nucleic acids will be held at the University of Ulm, from October 8 to 13, 1979.

The practical work includes: Heteroduplex analysis, Partial denaturation mapping of DNA, Secondary structure analysis of RNA, Cross-link reactions in nucleic acids, Molecular darkfield/brightfield electron microscopy. Instructors are competent researchers in the field.

Participants will be limited to 12 and selected from applicants having some experience with nucleic acid studies and/or electron microscope techniques. Limited funds will be available to cover travel expenses and/or a few stipends for accommodation. Applications should be sent to the Organisers, not later than August 15, 1979: Dr G. Klotz, Dr A. K. Kleinschmidt, Department of Microbiology, University of Ulm, Postfach 4066, D-7900 Ulm (Germany). W98(D)

**AWARDS**

**VETERANS ADMINISTRATION** announces the Second Round—Alcoholism Program. Emphasis on basic research to address etiology of alcoholism. Three year awards, up to \$100,000 per year. Applications accepted from VA and non-VA scientists, Ph.D.'s and M.D.'s. Research to be conducted in a VA Medical Center. Applications procedure: Letter of intent to apply due June 1, 1979. Ten page application due July 15, 1979. Decision on awards funding before January, 1980. Application should include the following: (1) Proposed investigation; (2) Curriculum vitae; (3) Two letters of recommendation. For further information contact: Dr Marcus Rothschild, VA Medical Center, New York, New York 10010 (212) 886-7500 X405. Dr Robert Allen (151F), VA Central Office, Washington, D.C. 20420. (202) 389 2124. W100(N)

**FELLOWSHIPS**

**UNIVERSITY OF WARWICK**  
**POSTDOCTORAL**  
**RESEARCH FELLOWSHIP**  
**IN INORGANIC CHEMISTRY**

Applications are invited for an S.R.C. Research Fellowship in the Department of Chemistry and Molecular Sciences for work on preparative, structural and catalytic properties of co-ordination and organometallic compounds of titanium, zirconium and hafnium in their lower oxidation states. The work is in conjunction with Professor M. G. H. Wallbridge and Dr G. R. Willey, and is for one year in the first instance with the possibility of renewal. Salary on the Research Range 1A scale, £3,883 to £6,555 (under review). Applications forms and further particulars may be obtained from the Academic Registrar, University of Warwick, Coventry CV4 7AL. UK. Please Quote Ref. 39/3A/79. 692(F)

### UNIVERSITY OF STRATHCLYDE

#### Applications are invited for a POSTDOCTORAL FELLOWSHIP IN ANALYTICAL CHEMISTRY

in the DEPARTMENT OF PURE AND APPLIED CHEMISTRY, tenable for two years, to work on the development and application of analytical techniques for the study of trace element metabolism during intravenous nutrition and in chronic haemodialysis with particular reference to selenium and chromium. Preference may be given to applicants with experience in atomic spectroscopy, as the principal techniques to be used will be flame atomic fluorescence and carbon furnace atomic absorption and emission spectrometry but consideration will be given to all candidates with a strong interest in the application of analytical techniques to clinical biochemistry. The post is sponsored by the Scottish Home and Health Department and will be jointly supervised by Dr J. M. Ottaway of the University of Strathclyde and Dr G. S. Fell of the Royal Infirmary, Glasgow.

The applicant will join an active research team involved in a wide range of trace metal metabolic studies in human medicine.

Commencing salary up to £5,637 per annum, under review. Range 1A of the national salary structure for research and analogous staff. Placing according to qualifications and experience. Superannuation benefit.

Further particulars (quoting R15/79) may be obtained from Dr J. M. Ottaway, Department of Pure and Applied Chemistry, University of Strathclyde, Cathedral Street, Glasgow G1 1XL, to whom applications should be sent as soon as possible.

694(E)

### THE ROYAL SOCIETY THE SMITH & NEPHEW FOUNDATION SENIOR

#### RESEARCH FELLOWSHIP

Applications are invited by the Council of the Royal Society for The Royal Society Smith & Nephew Foundation Senior Research Fellowship, established by means of a five-year grant from the Smith & Nephew Foundation for research in organic chemistry or biochemistry. The appointment will be tenable in any appropriate university department or research institution in the United Kingdom approved by the Council of the Royal Society. Candidates, who must be citizens of the United Kingdom or the Commonwealth, must supply the usual personal details and give two referees. Testimonials will not be considered. The subject of the proposed research, and where it would be done, together with the name of the head of the department, whose consent should first be obtained, must be stated.

The appointment which will be subject to the Society's general regulations governing research appointments, will be tenable for five years from October 1, 1979 (or another date to be arranged). Applicants should be under 40 on October 1, 1979. The present stipend scale is £8,031 by £252 to £8,787 by £249 to £9,036 per annum, and the point of entry will be determined by Council. Superannuation benefits will be provided. Some provision for research expenses will be available.

Applications should be made on forms to be obtained from the Executive Secretary, The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG, and returned by June 4, 1979.

685(E)

### IMPERIAL CANCER RESEARCH FUND RESEARCH FELLOWSHIP

A Postdoctoral Biochemist or Molecular biologist with experience in DNA sequencing techniques is required to assist in cloning and to sequence biologically significant regions of higher eukaryotic DNA.

The appointment will be for three years. Salary range £5,384 to £6,582 inc. L.A.

For further information telephone Dr A. M. Fried (01-242 0200 ext. 297). Applications with curriculum vitae and the names of two referees should be sent to the Secretary Imperial Cancer Research Fund, Lincoln's Inn Fields, London, W.C.2, quoting Reference 235/79 by June 4, 1979.

703(E)

### ST. PATRICK'S COLLEGE MAYNOOTH

#### DEPARTMENT OF CHEMISTRY

#### DUBLIN UNIVERSITY TRINITY COLLEGE

#### DEPARTMENT OF PURE AND ALLIED PHYSICS

#### POSTDOCTORAL RESEARCH FELLOWSHIP IN SURFACE SCIENCE

Applications are invited for the above post, funded by the National Board for Science and Technology, available immediately, tenable for a period of one year and renewable for a second, and final, year, at a salary of £4,190 per annum.

The Research Fellow will collaborate with Professor C. M. Quinn and Dr J. F. McGillo on experimental and theoretical studies of electron scattering from clean and adsorbate-covered single crystal surfaces.

Applicants should in the first instance, telephone the Staff Office, Trinity College, on Dublin 772941, Ext. 1678/1775.

W107(E)

### UNIVERSITY COLLEGE DUBLIN

#### DEPARTMENT OF BIOCHEMISTRY

#### Applications are invited for a POSTDOCTORAL

#### RESEARCH FELLOWSHIP

in the Department of Biochemistry, Belfield, Dublin 4. The successful applicant will help to develop a project (sponsored by Nordic Cold Storage Ltd.) investigating enzymatic changes occurring during long term storage of frozen meat products, and will therefore be expected to have adequate postgraduate experience in food science or in related fields. Appointment will be made on an annual basis for up to three years on a salary scale of £3,883 to £4,382 per annum.

Applications, with curriculum vitae and the names of two referees, should be sent, as soon as possible, but not later than May 31, 1979 to one of the following addresses: The Secretary, Department of Biochemistry, University College, Belfield, Dublin 4 or Mr W. J. A. Fearn, 1, The Sanctuary, Westminster SW1P 3JT, London, England.

714(E)

### UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL DEPARTMENT OF BIOCHEMISTRY POSTDOCTORAL FELLOWSHIP

Applications are invited for an M.R.C. funded post to investigate the properties of the muscarinic acetylcholine receptor on neuroblastoma cells in tissue culture; particular emphasis is to be made on the role of cyclic nucleotides in receptor function.

The post is for one year renewable for a further year at a starting salary of £3,883 per annum and the successful applicant will start on September 1, 1979 (or later as arranged).

Applications, including a curriculum vitae and the names of two referees, should be sent as soon as possible to Dr P. G. Strange, Department of Biochemistry, Medical School, Queen's Medical Centre, Nottingham NG7 2UH.

757(E)

### DALHOUSIE UNIVERSITY DEPARTMENT OF BIOCHEMISTRY

#### POSTDOCTORAL FELLOWSHIP

A position is available immediately to do cell cycle research with yeast. A background in biochemistry, molecular biology, cell biology, or microbiology desirable. Send Curriculum Vitae and names of three references to Dr R. A. Singer, Department of Biochemistry, Dalhousie University, Halifax, Nova Scotia, CANADA.

W105(E)

### CONFERENCES

#### CALL FOR ABSTRACTS BIOPHYSICAL DISCUSSIONS Second Discussion—May 1980

#### PROTEINS AND NUCLEOPROTEINS: STRUCTURE, DYNAMICS AND ASSEMBLY

The Biophysical Society will hold its 2nd Biophysical Discussion at Airlie House, Airlie, Virginia (near Washington, D.C.) on May 18-21, 1980. This Discussion will consider recent advances in understanding the principles of macromolecular structure and dynamics. Sessions will be devoted to: elucidation of structure by diffraction and spectroscopic methods; nature of forces stabilizing macromolecular structure; fluctuations in macromolecular structures; and mechanisms of folding and assembly. Experimental systems to be discussed include proteins, viruses, and organelles involving protein-nucleic acid interactions.

Prior to the meeting, all participants will receive a study book containing the full Discussion papers and poster abstracts. There will be no formal presentation of papers at the meeting, only a five-minute reminder followed by open discussion. A \$175 fee will cover registration, three days' room and board, the study book, and the final proceedings volume.

Papers submitted for the Organizing Committee's consideration are due as follows:

July 16, 1979—Preliminary abstracts (<300 words, to be reviewed and selected by August 1st)

December 1, 1979—Complete manuscripts (to be refereed and selected by mid-January)

The full edited proceedings of ca. 500 pp. will be published in hardback by Rockefeller University Press (\$20 prepublication, \$30 after October 1980). Identical text will be received by *Biophysical Journal* subscribers (1980 subscription, 12 issues, \$150). For these publications, remit to Order Service, Rockefeller University Press, P.O. Box 5108, New York, N.Y. 10249, USA.

For further information contact Valerie Parsegian, Executive Secretary, Biophysical Discussions, P.O. Box 30239, Bethesda, Maryland 20014, USA. Phone (202) 362-8184.

# *time flies...*

In the days when pocket watches and 'Double Alberts' were the fashion and British technology influenced the lives of millions of people throughout the world, the Company was in its formative years and proudly bore the name The British Drug Houses Limited.

Times and fashions change . . . the clockwork time piece gives way to electronic wizardry, this Company in keeping with the modern idiom is known as BDH . . . but one thing is constant, British technology is still pre-eminent.

The unique blue LC display in the digital watch is the result of collaboration between BDH, Professor Gray and his team at Hull University and the UK Royal Signals and Radar Establishment.

BDH offers manufacturers the finest range of LCD materials in the world.

## Happy Endings.

Your DNA research should have a happy ending. That's why Miles has developed enzymes that cleave and splice DNA easily and accurately.

All of our restriction nucleases—such as *Eco* RI—specifically cleave DNA within certain well-defined base sequences. And to make sure you're happy with the cleaved ends, we include a sample of lambda DNA for verification of enzyme activity... so you never risk your research DNA. The results of our stringent specification tests are reported on the chemical

credential that accompanies each order. No surprises, no mystery.

And, for recombinant DNA, we have terminal transferase to add dA and dT segments and DNA ligase to splice fragments together.

Restriction nucleases, terminal transferase, DNA ligase. Miles enzymes for happy endings... and beginnings.

Please supply more information about:

- ☐ Restriction nucleases   ☐ DNA ligase   ☐ Terminal transferase  
☐ Please send a current Miles Biochemical Catalog.

# UNRESTRAINED CREATIVITY

**The ALZET® osmotic minipump  
... control complements chemistry  
in the quest for specificity.**

Since Ehrlich's time, chemistry has been the dominant creative force in the quest for specificity in the action for drugs. Yet true specificity is elusive, and even the hormones show undesirable and unsafe actions when their concentrations in blood or tissues are uncontrolled. The physiology of hormonal secretory control systems teaches how control has complemented chemistry in nature's quest for specificity and continuity in hormonal action.

The ALZET® osmotic minipump now gives you unprecedented, round-the-clock control for one and two weeks over the entry of drugs or hormones into the bloodstream of unrestrained lab animals. With

the incredible minipumps, you can attain gland-like control, allowing you to optimize both the specificity and the continuity of action of the agents you use in your research.

Creativity in applying the principle of control to complement chemistry is yours for the doing. Examples of such creativity are illustrated in the rapidly expanding Alzet® osmotic minipump product bibliography. May we include your abstract or paper reporting work based on minipump use? For a copy of the bibliography, or to order, call the following toll-free number: 800/227-9953. In California and Hawaii, call collect: 415/494-5067.

**Guide to authors**

● Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.

● Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.

● Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.

● 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words.

Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

**Manuscripts** may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the *Système International*. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to  $e^a$  if 'a' is more than one character.

**References** are indicated by superscripts in the text. See any contemporary *Nature* for style, but note: (i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

**Artwork** should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

*Nature's* publishing policy is outlined in 258,1 (1975) and 264, v, 11 Nov. (1976).

# Just a minute....

The Titertek® Multiskan is an eight-channel photometer designed to measure simultaneously the absorbances of the contents of eight wells (one row) of a flat bottomed microtitration plate.

The vertical light path is unique and ensures that the measured absorbance is dependent only on the amount of absorbing substance, not on its concentration.

A microprocessor based system controls the reading process which is automatic and takes only 60 seconds for 96-wells.

It has been designed specifically for Enzyme-linked Immunoassays but has many other applications.

## A select committee to be kept

WITHIN a period of weeks rather than months the UK House of Commons is likely to start discussing changes in procedure, and high on the list of priorities will be a re-organisation of the select committee structure. There is a wide measure of support in parliament for the re-aligning of committees along ministerial lines, and were this to come about the Select Committee on Science and Technology would be disbanded; scientific issues would then be the concern of, at the least, the select committees on agriculture; defence; education, science and the arts; energy; environment; industry; and social services. Professors Ziman and Denbigh recently expressed the view of the Council for Science and Society that this would be a retrograde step (10 May, p 100).

This is a view which will be widely shared by scientists and technologists. The present committee has come in for its fair share of criticism from us and others in the past, but at least it has provided a fairly effective way by which the communities of science and technology could make contact with parliament, in an almost totally non-partisan way, on matters of concern. In none of the proposed new

committees will scientists find their interests and worries given anything like the same attention—least of all in the education, science and arts committee, where education will surely swamp everything else.

The scientific and technological community, almost by its very nature, has never had more than a handful of its number in the Commons. During its time, however, the select committee has turned up several non-scientists who have taken an active and highly intelligent interest in scientific matters; in the new order there is unlikely to be any incentive for such people to come forward.

Finally, the assumption made in the new scheme is that the way the government divides its ministerial responsibilities is the way that major national issues divide. This is simply not true in the scientific and technological field. Who would look at genetic manipulation? The impact of microprocessors? Support for innovation? Scientific manpower problems? Training for the engineering profession? Climatic change? These are all matters in which parliamentarians ought to be informed. And none of them falls neatly into one department's remit. □

## Elitist patronage—and rightly so

FIVE years ago the German pharmaceutical company C. H. Boehringer Sohn of Ingelheim invited a group of biologists, medical researchers, and philosophers to spend a few days together in a well-appointed Schloss far from the pressures of colleagues, students and telephones. The group brooded on the question of creativity, and a report of the deliberations was later published (*The creative process in science and medicine* edited by Hans Krebs and Julian Shelley; Excerpta Medica).

The indefatigable Dr Shelley, Boehringer's Director of Clinical Investigation, has just stage-managed a second symposium with a broad interdisciplinary sweep. As if the first of them were not wide-ranging enough, the second was entitled 'Structure in Science and Art', and this time the biologists and philosophers were joined by an architect, a professor of English, two composers, a novelist, three physicists, a concert pianist and an art historian. This heady brew resembled nothing so much as a High Table of High Tables in the Oxbridge tradition, except, of course, that with a battery of microphones and an army of typists waiting to transcribe every slightest remark, conversation was considerably more elevated than standard High Table fare concerning the foibles of students, the price of books and the run-down condition of the college gardens.

This is no place to try to summarise the presentations and discussions, which roamed over perception, the ob-

server in the universe, structuralism in the novel, D'Arcy Thompson's mathematical analysis of form, Breughel's 'Icarus', Schoenberg's piano music and much else besides. But it is appropriate to ask whether at the end of the day any threads, however tenuous, had been laid across the yawning chasm between the sciences and the arts. Does 'structure' offer any common ground—does, for instance, appreciation of the structure of a Mozart concerto help those looking for structure in biological molecules? On the face of it, no.

Those who read the proceedings of this symposium in the hope of seeing new lines of thought emerge, spanning the disciplines, will almost certainly be disappointed. But sensitivity to a wide range of subjects probably does help to enrich work in one's own particular discipline. And occasions such as this symposium do help to heighten that sensitivity of those fortunate participants.

It is a commonplace to say of a conference that the real work was done outside the formal sessions. In this case, however, there is little doubt that this was true; the new contacts, the informal conversations will count for more than what was actually said to the microphones. Mercifully the sponsors seem to appreciate this, and look for no agreed conclusions, no statement to the world out of it all. It is enlightened patronage, of an elitist sort that few dare to pursue these days. □

## A week of nuclear decision in the United States and Europe

# Columbia University drops plans to operate reactor

LAST week the University of Columbia in New York withdrew a request for a permit from the City of New York to operate a teaching reactor built on the university's Morningside campus in 1969. The university also agreed to withdraw a federal lawsuit, filed jointly with the Department of Justice, challenging the city's jurisdiction over nuclear reactors and radioactive materials.

This move follows a decision by the Faculty of Engineering at Columbia University to accept a request from the president of the university, Dr William J. McGill, not to put the reactor into operation.

Dr McGill had previously resisted moves by members of the local community to prevent the reactor from operating because of health dangers which, some had claimed, would be posed in the case of an accident. However, according to a statement made at a public hearing two weeks ago, Dr McGill said that he had changed his stance mainly in response to public reaction to the Three Mile Island nuclear accident. The university's faculty of engineering has agreed to "acquiesce" to the president's decision. Individually, however, many faculty members disagree with the action, claiming that only increased familiarity with reactor technology will enable operators of the future to avoid the type of mistakes made at Harrisburg.

Students at the university, on the other hand, who have been campaigning against the reactor for many years, claim that the action does not go far enough. They want the reactor, which was constructed in the 1960s but has never been operated due to a succession of legal disputes, to be dismantled, and effort to be transferred to solar energy research.

The teaching reactor is a Triga Mark II reactor, and is licensed to operate up to 250 kilowatts, although university officials say that it would only run at an average of 1 kilowatt. The reactor itself cost about \$500,000, and was financed by the National Science Foundation, with another \$500,000 being spent on the surrounding building. Similar reactors are already in operation in about 60 universities in both the US and overseas.

Earlier this year, after a series of legal battles over who should have the right to licence the reactor Dr McGill announced that the reactor would still go into operation but not until all the legal aspects had been resolved.

Following the Three Mile Island accident, however, and subsequent

student demonstrations on the Columbia campus, Dr McGill announced that he was going to ask the faculty of engineering to reconsider its plans to operate the reactor. The opposition to the university reactor, which he had previously envisaged to be a political problem, "was clearly revealed during the last week in March and the first week of April as a human problem of mounting seriousness," Dr McGill told the public hearing in New York.

"The Triga issue suddenly acquired the potential to tear the campus apart in an explosion of fear and apprehen-

sion. The larger interests of safety and well-being affecting everyone at Columbia University required that I act immediately, and I did so."

Faculty members, while agreeing to go along with the president's decision, are critical both of its implications, and of the way that the decision was taken. "The president's decision was a political one not an educational one; the decision not to operate the reactor is a loss to the country and to the educational community that we cannot afford at the present time," Professor William Havens, director of the university's nuclear science programmes said last week.

The reactor may still be operated in the future, if the general opposition to nuclear power should change, according to Dr Peter J. Likens, dean of the university's school of engineering. "We might seek to reconsider that decision and activate it if the social circumstances mitigate it."

Meanwhile students taking nuclear science and engineering courses at the university may be sent out to the medical research reactor operated by the Brookhaven National Laboratory on Long Island to gain first-hand experience of reactor technology.

David Dickson

"If there's no reactor to learn from, there'll be nobody to build them!"

## Punitive damages for Silkwood contamination

IN a decision which could have far-reaching implications for the US nuclear industry, a jury in Oklahoma City last Friday awarded damages of \$10.5 million to the three children of Karen Silkwood, an employee of the Kerr-McGee corporation who, it accepted, had been contaminated by plutonium while working in the company's nuclear fuel processing plant.

Miss Silkwood, a laboratory technician in the plant and an activist in the Old Chemical and Atomic Workers Union, was killed in a car accident in 1974 on the way to a meeting with a newspaper reporter at which, she had said, she would produce evidence that Kerr-McGee had carelessly exposed employees to plutonium. After the accident investigators found traces of plutonium in Miss Silkwood's apartment but no papers were found in the car in which she had been travelling.

After a 10-week trial, the jury found the company negligent in the contamination of Miss Silkwood and her apartment, and rejected the charge that she had contaminated herself with plutonium stolen from the plant in

order to incriminate the company. They awarded Miss Silkwood's estate \$505,000 in actual damages, and \$10 million in punitive damages. During the trial, attorney's for the estate argued that working conditions inside the plant were inherently unsafe, and that workers had not been told that plutonium could cause cancer.

Company officials reported that they had informed the Atomic Energy Commission that they had been unable to account for about 40 lbs of weapons-grade plutonium, and believed that the material was trapped in pipes in the plant; the prosecution attorneys contended that the company's inability to account for the plutonium was further evidence of its negligence. The Kerr-McGee plant at which Miss Silkwood worked has since been closed down.

Agents for Miss Silkwood's estate are bringing a further lawsuit against the Oklahoma City Police Force, the FBI and Kerr-McGee concerning the circumstances of her death and a high OCAW official had called for a special government prosecutor to re-open the case. □

# Switzerland increases control of nuclear power

THE referendum on the law governing atomic power in Switzerland last week—at which voters approved the government's revision by more than two to one—was hardly the centre of a historic debate. In comparison to the heated debate before the 18 February vote on the nuclear issue—which by a narrow margin upheld the old law rather than one which would have prevented further development of nuclear power—the political temperature has reached an all-time low. All the major parties and organisations either recommended voting for the revision, or refused to take up positions. There has been no propaganda clash. The newspapers are practically void of announcements, and the usual stream of press conferences and meetings is absent.

The main reason for this lack of interest is that the revised law represents a compromise which satisfies no-one. The nuclear lobby is unenthusiastic about the restrictions but reckons "it could have been worse". The only positive aspect it discerns is the clarification of the waste disposal problem (5 April). The anti-nuclear group's general attitude is "better than nothing", although one section voted no, on the grounds that if the revision was rejected, a new revision could only be even more restrictive.

The proposals embodied in the revised law contain enough seeds of discontent to ensure that the peace will probably be only a lull in the storm.

- The granting of skeleton permits for new nuclear power stations, and of construction permits for those already planned—both to be done now by parliament, rather than the cabinet alone—will depend on:

- the demonstration of electricity demand; and
- safe nuclear waste management.

That the law leaves much latitude in the interpretation of these points became clear at a series of hearings in Bern organised by the Swiss Energy Foundation, the main "soft energy" group and leader of the environmentalist opposition to nuclear development. Officials of the various government de-

partments which will be required to put the revised law into practice were interrogated by representatives of both the pro and anti-nuclear groups on their interpretation of the demand and waste management paragraphs, as well as on the proposed procedure for nuclear power stations which already have site but not construction permits.

The transcripts of the hearings<sup>1</sup> indicate that the "demonstration of demand" will become a hard-fought issue in future. How can demand be demonstrated when Switzerland is literally "throwing away" one-third of all the energy it produces because of inefficient systems, poor insulation, lack of incentives for energy saving, etc.? Is not the level of demand really a political question? What reserve capacity is needed to meet short-term abnormal demands or break-downs in functioning units? To decide these questions it is proposed to set up an Energy Commission, but the problem is how to make sure that it is unbiased and uninfluenced by the powerful lobbies.

The "demonstration of safe nuclear waste management" also leaves many questions open. Will it be possible, even with the revised law, to test drill for underground repositories against the will of the local population, without excessive delays? What does safe mean, and how can safety be demonstrated in future waste management when so much of the process takes place outside the country—is what is safe for them, safe for us? Is the question of disposal, particularly of high-level waste, so controversial among scientists that it can hardly be assessed by the present Waste Management Working Group, largely made up of civil servants? How can a waste disposal project be worked out within the next five years (when the first power station falling under the new regulations will be finished) when other countries ahead of Switzerland in R & D envisage 10 more years at least?

Geoff Milnes

## Gorleben nuclear waste facility scrapped

In West Germany last week the premier of Lower Saxony, Herr Ernst Albrecht, announced that he will not grant approval for the building of a nuclear waste reprocessing and disposal facility at Gorleben. Speaking on television he said the decision was not a technical

one—he believed that the plant would be safe—but he had to take account of the weight of public opinion. However, test drilling in salt domes at Gorleben (see below) will continue.

For a detailed review of the decision, see page 283.

## EEC Commissioner opens European nuclear fusion centre

DR GUIDO Brunner, member of the European Commission for Energy, Research, Science and Education, laid the foundation stone for JET, the Joint European Torus, at the Culham Laboratory, UK, last week. During the ceremony, Dr Brunner described JET as a "leading project in the world" in the field of fusion research.

JET's world lead, however, has been

eroded by the delays to the start of the project caused by the two year negotiations in 1975-77 between EEC member states over where it should be sited. The delay has given its nearest rival, the Tokamak Fusion Test Reactor, at Princeton University, US, an eighteen month lead.

The total cost of building JET is estimated at about 200 million Euro-

pean Units of Account (at January 1979 prices). The date for completion is set at the end of 1982 and subsequent annual operating costs are expected to be about £20 million at today's prices. The JET team, which will be drawn from fusion laboratories all over Europe, is expected to be about 320 strong including 120 scientists and engineers. At present

130 people are employed on the project, half of them under Euratom contract, and half of them by the UKAEA which runs Culham.

According to Dr Hans-Otto Wüster, Director of the JET Joint Undertaking and Dr Paul Rebut, leader of the JET design team, there are some worries that JET will not attract enough high calibre fusion physicists to make up the rest of the team. One problem is that during the lengthy debate over where to site the project, almost half the design team returned to their home laboratories. Although many of these have now returned to JET, it is feared that the salaries being offered by Euratom are insufficient to entice French and German scientists to the Oxfordshire countryside.

Initially, experiments on JET will be with a D-D plasma. If these are successful, then the project will move into the "radioactive stage" by 1983-84. This will involve beam-plasma D-T operation resulting in neutron production which will activate the walls of the vessel containing the plasma. Dr Wüster said that this stage of the experimental programme would not commence without further agreement. He also assured that the radioactivity produced would be between ten and a hundred times less than that produced by nuclear fission. As the amount of radioactive material created would be very small, he thought that energy produced from fusion could prove "environmentally advantageous".

The decision over whether or not to enter the 'radioactive stage' is bound to be difficult, according to Dr R. J. Bickerton. There is already one school of thought which would like to proceed to reactor conditions as quickly as possible and another that would rather understand the plasma physics thoroughly first. This difference in opinion is to some extent reflected in the discussions which have already started on the machine to follow JET. Dr Bas Pease, Director of Culham Laboratory, thinks that the next machine should aim at demonstrating a net production of electricity. "I favour the view that we should attempt this after JET, but I can't yet say that I have persuaded a majority of colleagues of that view", he said.

The Euratom countries have already set up a Next European Torus Study Group to discuss the next machine. According to Dr Brunner, however, Europe may not be able to afford to build JET's successor alone. It is therefore cooperating in the INTOR Study Group, under the auspices of the International Atomic Energy Agency, which is looking at the possibility of the USSR, Western Europe, the US and Japan building a worldwide machine.

## US foreign research rises to \$1.5 billion

THE vast majority of research carried out by US private corporations in foreign countries is concerned with developing products for local market conditions, rather than with longer term basic or applied research goals, according to a survey conducted by the National Science Foundation.

Research and development carried out abroad by US corporations increased by 41% between 1974 and 1977, to a total of \$1.5 billion, the survey reports. This represents about 7% of the total expenditure on R&D by private companies, which increased by 32% over this period.

The most substantial increase in overseas R&D occurred in the pharmaceutical industry, with many companies conducting trials of new drugs abroad in order to take advantage of more liberal conditions on foreign testing introduced by the Food and Drug Administration in 1975. Thus between 1974 and 1977, the amount of R&D conducted by pharmaceutical companies abroad more than doubled, compared to an increase of only 34% in the funds spent at home over this period (although the report adds that foreign and domestic R&D are now increasing at about the same rate).

The NSF survey says that in companies with world-wide research capabilities, the US laboratory usually takes the lead in overall technological development, with the foreign labora-

tories providing specialised development for particular market conditions. The foreign R&D facilities of these companies therefore conducted primarily development projects, even though basic and applied research accounts for almost one quarter of total domestic R&D spending by US companies.

Interviews carried out with the managers of 18 large private corporations revealed only one case in which a company reported any expenditure on basic research conducted outside the US. Two other companies reported that their foreign research facilities carried out some applied research work.

Looking to the future, the NSF study says that an expected increase in overseas sales by US corporations is likely to cause such companies to open new foreign R&D facilities or to expand existing operations, with increased sales, rather than other factors such as lower research and development costs, providing the main motivation for such developments.

The report also notes that several R&D directors outside the pharmaceutical industry said that increasing regulation by bodies such as the Occupational Safety and Health Administration and the Environmental Protection Agency in the US would tend to cause companies to move R&D resources to other countries where operations would not be affected as much. □

## University of Houston expels professor

THE University of Houston in Texas is refusing to renew the contract of Professor Archer J. P. Martin, joint winner of the Nobel prize for chemistry in 1952 with R. L. M. Synge for his work on chromatography, on the grounds of "inadequate productivity".

Professor Martin, who is 69, was appointed to the Welch chair of chemistry in 1974, and until last year held a joint appointment at the University of Sussex, where he was carrying out research on protein separation sponsored by the Medical Research Council.

The University of Houston requires that after a faculty member reaches the age of 64, his or her tenure must be renewed annually. Last year the university told Dr Martin that the Department of Chemistry did not consider he had published enough scientific papers, and that his appointment would not be renewed.

Professor Martin told *Nature* last week that when he took the post, he had not been aware that there would be little money for research assistants or experimental facilities and consequently that he spent most of his time in Houston planning experiments to be carried out in Sussex.

He accepts that he has published very few scientific papers over the past five years from his work at Houston, but claims that he has no desire to rush into print unnecessarily (his total scientific output is about 70 scientific papers). According to Professor Martin, the university did not take into account papers produced from the work at Sussex in considering whether his contract should be renewed.

A faculty committee, to which Professor Martin protested at his dismissal, came to the conclusion that the terms of his appointment had not been initially made adequately clear, and recommended that he be kept on the staff. However, two weeks ago Professor Robert H. Walker, Dean of the College of Natural Sciences and Mathematics, informed Professor Martin that the university had no power to keep him on unless the Department of Chemistry changed its mind. According to Dr. Walker, the university does not set any specific target on the number of papers which a research worker is expected to produce each year but, he says that there is nevertheless "a certain expectation of productivity". □

# Congress goes easy on science—so far

A KEY subcommittee of the US House of Representatives last week recommended that \$19 million be cut from the budget request for the National Science Foundation which had been submitted by President Carter. Although this represents a reduction of almost 2% in the \$1,006 million request submitted. It is considerably less than the \$44 million reduction which the same subcommittee wanted made in the NSF's budget last year.

The subcommittee's recommendations, which have to be accepted by the full committee of Appropriations before being debated on the floor of the House, would delete \$10 million from the agency's basic research programmes out of a requested total of \$793.3 million, \$3 million out of the \$62.4 million requested for the applied science and research applications programmes, and \$3 million out of programme management.

The subcommittee made no mention of the ceiling which Congress placed on salaries of NSF grant-holders last year, leading some to speculate that the ceiling might be lifted during conference with the Senate. However, neither did it add any extra money for research on earthquake hazards, for which the House last month authorised spending to be increased from \$18.3 million to \$22.8 million.

NSF officials were relieved that the cuts were not greater (a move to make an additional \$12 million cut is said to have been headed off in the subcommittee meeting). However, the real tests will come in the middle of next month when the NSF request is debated both on the floor of the House—where the Appropriations Bill has already been cut back by \$14 million—and in the Senate Appropriations Subcommittee chaired by Senator William Proxmire. □

## Funds denied for nuclear waste

THE House Armed Services Committee has voted to cut off all funds for an experimental project to store nuclear waste in salt caverns near Carlsbad, New Mexico.

The project, known as a waste isolation pilot plant (WIPP) has been under development by the Department of Energy for some time. The site was chosen in 1976, and if permission to build the plant is granted, the site could be ready to receive both transuranic wastes from the defence programme and commercial waste from nuclear reactors within a few years.

The scheme has generated intense controversy in New Mexico. Supporters say the WIPP facility would bring new jobs and extra income to the area. Opponents claim it would restrict access to other valuable resources, such as potash, and also point to doubts over the suitability of salt as a disposal medium.

The House Armed Services Committee voted against further funding for the WIPP facility not on environmental or scientific grounds, but because it felt that a plant initially intended for defence wastes should not also be used for the disposal of commercial wastes. Meanwhile, the Senate Armed Services Committee has agreed to let funding for the project stand in the Department of Energy's budget request, but on the understanding that no commercial spent fuel should be stored at the WIPP site.

The outcome will depend on what happens in floor debates and during the conference between the House and the Senate. Another factor will be the President's announcement soon on federal waste disposal, following a report on nuclear waste management prepared last year by an interagency review group.

Meanwhile, the Senate and the New York State Assembly announced last week a curb on the amount of nuclear waste that can be stored in the state's West Valley facility, which has been closed since 1972. □

## Senate committee kills fast breeder

A NEW political confrontation over the future of the liquid metal fast breeder reactor project at Clinch River in Tennessee seems certain after the Senate Energy and Natural Resources Committee last week accepted a proposal from Senator Dale Bumpers of Arkansas to kill the \$2.6 billion project. The House Science and Technology Committee has already voted to continue.

President Carter has consistently been opposed to the plan, initially on the grounds that the use of plutonium in fast breeders increases the chances of nuclear proliferation. More recently, the President has claimed that the Clinch River design was obsolete after new advances in technology, and that with a slowing down in growth of energy demand, the need for fast breeders is not so urgent.

The General Accounting Office, however, which carries out studies of particular issues for the Congress, disagrees with the President. In a report published earlier this month, the GAO stated that the Clinch River project would be a "logical and prudent step".

In pledging its support for the project, the House Committee added \$184 million to the authorisation request for the Department of Energy so that the project could proceed. Senator Bumpers' proposal, which has been accepted by the Senate Energy Committee, is to terminate the breeder project by 1 October, but to authorise a design study for a larger breeder test plant. "Clinch River is dead and the sooner we admit it, the more the American people will applaud us for doing it," Senator Bumpers said. □

## Technical aid restored to UN bodies

THE US Senate voted last week to repeal a decision, taken in the heat of the closing hours of the 95th Congress last autumn, which effectively cut off all US contributions to bodies in the United Nations system.

The earlier decision took the form of an amendment, proposed by Senator Jesse Helms of North Carolina, which specified that none of the funds which the US contributes to bodies such as the World Health Organisation and the Food and Agricultural Organisation could be used for the purpose of "technical assistance".

The UN bodies subsequently told the US State Department that it could not

accept contributions under those conditions. Last week, however, in passing the Foreign Relations Authorisations Act for 1980, the Senate in effect repealed the Helms Amendment, following a similar move in the House of Representatives.

The Senate also defeated, by 54 votes to 35, a further amendment from Senator Helms which would have revived the issue by refusing to include money for technical assistance in the mandatory contributions which the US pays to the UN bodies. Senator Helms said it was a matter of whether the Senate wished to impose an 'International Tax' on Americans. □

# Pesticide resistance on the increase, says UNEP

RESISTANCE to pesticides has been spreading so rapidly among pests that no manufacturer cared to offer a new pesticide to the World Health Organisation for safety testing in 1978. It now takes millions of dollars to test the safety of new chemicals and often within months pests start developing resistance to it. WHO recently reported that it is now cutting down its field staff involved in safety testing of pesticides.

Reflecting these events, this year's State of the Environment Report to be released by the United Nations Environment Programme on the occasion of the World Environment Day (5 June) will focus upon the increasing dangers posed by pesticide resistance. The report makes quite frightening reading.

It points out that in 1965, the Food and Agricultural Organisation listed 182 resistant strains of arthropod pests; in 1968, it listed 228 resistant species; and now its latest survey of 1977 lists 364 species.

There are now 223 agricultural pests resistant to nine of the major groups of pesticides. Many of these, says the UNEP report, "are major pests of major crops, such as cotton bollworm, the boll weevil, and the leafworm of cotton, the rice stem borer and the brown plant hopper, the Colorado beetle of potatoes, spider mites of fruit and glasshouse crops, and cutworms and weevils of cereals".

Up to 1970, very few resistant plant pathogens had been observed. But with the introduction of new systemic fungicides, the resistance problem has crept in, and now more than 35 species of plant pathogens have been reported as resistant.

Rodents, which destroy crops, are also becoming resistant to rodenticides. Latest FAO figures show that seven species of rodents, including two important and widespread species, *Rattus rattus*, and *Rattus norvegicus*, have developed resistant strains.

If there is any ray of hope it seems to be with weeds, which have not yet shown any sign of developing genetical resistance similar to that occurring amongst insects—even though herbicides now account for some 50% of all pesticides applied. For long-lived perennial and vegetatively reproducing weeds, says the report, "the potential for development of genetical resistance seems low bearing in mind that experience with insects and other classes has demonstrated that in the field many generations must pass before such resistance reaches notice-

able levels".

The most worrying situation is in the field of public health. WHO figures cited in the UNEP report show that there are now 121 resistant strains of insects important to public health campaigns compared to 102 in 1968. In 1969, 15 species of anopheline mosquitoes were resistant to DDT and some 37 to dieldrin. In 1976, some 43 species were known to be resistant to dieldrin, 24 to DDT, five to organophosphates like malathion, and two to carbamates.

Resistance to insecticides is now found amongst anopheline mosquitoes in 62 countries out of 107 where there is malaria. In several parts of the world there has been a massive resurgence of the disease, with some countries showing a 30-40 fold increase in the number of malaria cases since 1968-70.

Switching over from DDT to other insecticides like malathion has not proved easy. Most of the substitutes of DDT are both much more toxic and much more costly. India's malaria control programme alone consumes nearly 60% of the Indian government's health budget.

Amongst culicine mosquitoes, vectors of such diseases as yellow fever, filariasis and dengue, resistance has increased from 19 species in 1968 to 41 species in 1975. Other important vectors such as houseflies, black flies and fleas are also becoming resistant. The house fly, says the UNEP report, seems to be the insect "with the greatest ability to develop resistance to insecticides over the widest geographical area". A total of 121 resistant strains of housefly were reported in 1975.

Research on pest control agents with novel modes of action like chemosterilants, hormones and growth inhibitors, and biological agents like bacteria, viruses and fungi, has been hailed in the belief that pests would be less likely to develop resistance to them. The UNEP report however points out that this hope is ill-founded.

Resistance has already appeared to hormone-based pesticides where little resistance had been expected. "New compounds such as growth regulators and microbial pesticides have not been in use long enough or on a wide enough scale to show perceptible resistance, but here again as with chemosterilants, it has been possible in the laboratory to develop resistance by artificial selection."

The flour beetle, *Tribolium*, has not

only developed multiple resistance to conventional pesticides but also acquired significant cross-resistance to the growth inhibitor, methoprene. It has also been shown that houseflies can become resistant both to the spores of *Bacillus thuringiensis* and to its toxin. *B. thuringiensis* is expected to become an important biological control agent.

What then is the solution to pest control? UNEP points out that the classical alternative approach of changing the pesticide when faced with the problem of resistance is a practical solution only in the short term. Alternative pesticides need to be developed but in the long term, the situation is such that it requires the development of alternative strategies.

Instead of total reliance on just one type of control agent like chemical pesticides, UNEP favours the concept of 'integrated pest control.' This would include elements of chemical pest control, environmental control of breeding habitats, genetic control techniques, biological control, behavioural control using sex pheromones and related compounds, and breeding of resistance in crops and animals.

Integrated pest control strategies will have to be specific to a pest in a specific environment. This will require considerable research. An FAO/UNEP panel of experts on integrated pest control has over the last few years developed a Global Programme for Integrated Pest Control in relation to various priority crops like cotton, rice, sorghum, maize, millet, roots and tubers and grain legumes, and is now extending this to vegetable crops.

Studies conducted in South America using integrated pest control techniques on cotton—the highest consumer of insecticides in agriculture—shows that the quantity of chemicals needed can be reduced by a third, thus cutting down costs and health risks and increasing productivity. But while this system of integrated pest management has been considerably developed, both in theory and in practice, as regards agricultural pest control, the UNEP report claims that extensive research programmes are still needed to apply it to public health vector control.

The switch from chemicals to the new packages of integrated practices is therefore likely to take a considerable time.

Anil Agarwal

# Ecology groups combat Chinese irrigation plan

CHINESE plans to divert water from the Yangtze to irrigate northern China have run into cautiously expressed but clear opposition from Chinese environmentalists. A recent meeting of the Chinese Society for Water Conservancy, officially described as an "academic discussion" on the plan, concluded that in the past, "our improper water control plans violated objective laws". Any plans to divert the Yangtze, they stressed, must be considered not from a purely engineering point of view, but should also take into account possible ecological changes produced by the scheme.

As far as the engineers are concerned, plans still remain flexible. A national forum held in Tianjin at the beginning of April discussed three possible routes: the "Western route" from the mountainous upper reaches of the Yangtze via "snaking tunnels" to north-west China; the "middle route", via a projected canal which would cross the Hwang-Ho near Zhengzhou; and the "eastern route" which would roughly follow that of the Grand Canal built by the Emperor Yang Di in about 600 AD.

All three routes, the forum decided, were practicable, although each plan still required some improvement. Construction of the western route, it was concluded, lay beyond China's capability at the moment. The eastern route, first announced in August 1978, although feasible, attracted considerably less support than the middle route, which appeared to be the choice of the Yangtze Basin Planning Commission. A spokesman for the commission told the forum that this route would involve the construction of a 1,000 km canal from the Banjiangkou reservoir on the Han river (a major tributary of the Yangtze), as far as Peking, via the foothills of the Funiu range and the Nanyang basin in southern Henan, approaching Peking on a route parallel to the Peking-Canton railway. When completed, he said, the scheme would irrigate 4,666,000 ha of farmland, bringing an average of 10,000 million m<sup>3</sup> water annually to the Hai river basin, thus equalling the annual flow of the entire Hai system.

However, it might seem strange to divert water from the Yangtze across the Hwang-Ho. Why not simply irrigate north-west China with water diverted from the Hwang-Ho? The reason is that the mean flow rate of the Yangtze

is 34,000 m<sup>3</sup> sec<sup>-1</sup>, considerably greater than the 1,500 m<sup>3</sup> sec<sup>-1</sup> flow rate achieved on average by the Hwang-Ho.

The spokesman admitted, however, that there was one major disadvantage to this plan. The annual output of the Danjiangkou hydroelectric station would have to be reduced by anything from 700 million to 1,700 million kWh annually. This, however, he claimed, could be compensated by the Gezhou power station now under construction further westward.

At least one water conservancy specialist, a delegate from Qinghua University, showed some support for the plan. He noted that large areas of rock fissures and sandy structures beneath Peking city could be used as an emergency water store, while some 15,000 sq km of "abandoned river beds" north of the Hwang-Ho could be used to store 39,000 m<sup>3</sup>. In general, however, the conservationists are somewhat cautious. The "academic discussion" of the Conservancy Society pointed out a number of factors which demand further consideration. Would the diversion, they asked, cause secondary salinisation and alkalisation of the soil? Further, what would happen in drought years? In 1978, droughts in the middle and lower Yangtze basin and the consumption of large quantities of water for irrigation led to a back-flow of sea water into the Yangtze estuary, so that, for a time, the population of Shanghai was obliged to drink brackish water, while at Chongming island, which supplies agricultural and market-garden produce to Shanghai, cultivation was seriously affected. Any proposed diversion of the Yangtze, they stress, "must conform to the law of nature and the economic law".

Vera Rich

## Hungarian scientists want better links with government

HUNGARY'S Academy of Sciences has adopted a new constitution which calls for greater accountability from government departments and industry.

Although in July 1969 the Central Committee of the Hungarian Communist Party affirmed, in a startling change of direction, the need for complete freedom in scientific research and an atmosphere of free and uninhibited discussion among scientists, economic demands, both national and within the Comecon framework, have led to a policy of closer integration between research and production. This the Hungarian scientists seemed perfectly prepared to accept. Last year's General Assembly of the Academy stressed the need for greater selectivity in research subjects, taking into account the current "social needs".

Nevertheless, this linkage does not seem to be operating as smoothly as hoped. There are considerable delays (running into years and sometimes decades) in the introduction of Hungarian patents and inventions in practice. This is not only due to bureaucratic delays; last summer, the president of the National Patent Office, Emil Tasnadi, told the prestigious political and literary journal *Elet es Prodalom* that the fault lay largely with the scientists. There are some 35,000 scientists in Hungary, he said, but their sole aim is to achieve academic degrees: the titles of Candidate (PhD) and Doctor bring with them, respectively, a life-long stipend of 500 and 1,000 forints per month. Since these degrees are earned through the publishing of articles and books, he said, and not by inventions, only six researchers in every thousand actually have a patent to their credit.

While not actually answering Tasnadi directly, Dr Janos Szentagothai, the president of the Academy, took the opportunity of this year's General Assembly to state the scientists' case. Links between research and production have come closer in recent years, he noted approvingly; nevertheless, the situation is by no means satisfactory. The various departments of the Academy duly make the proper recommendations to the production sector—but receive little or no feedback. Frequently, he said, the scientists do not know if the recommendations have even been discussed.

The new constitution of the Academy, adopted by the General Assembly on 11 May, and made retroactive to last April, demands that this situation should be rectified. □

**Harvard makes mathematics mandatory:** In a far reaching revision of its undergraduate curriculum Harvard University will demand mathematics proficiency from its entire student body. All Harvard entrants will be required to show proficiency within their first year in three areas: applications of the function concept to the real world; probability and statistics; and in the use of time-shared computers. The mathematics requirement will have further effects in raising the level of instruction of the new science requirements for non-science students. All students will be required to take a one semester course in a physical science ("predictive and deductive analysis and quantitative treatment of data") and a one semester course in a biological science ("descriptive treatment of complex historical or evolutionary systems"). Harvard's move, because of its great prestige in the US, is expected to have widespread implications for the whole of US higher education.

**Spanish dockers block uranium import:** The Spanish dockers union has boycotted the vessel *Covadonga* carrying nuclear fuel from the US for a power station under construction at Leimoniz in the Basque country. The boycott applies to every port in Spain and the vessel was diverted to Bordeaux. The Spanish unions appealed to unions throughout Europe for solidarity and French dockyard workers refused to handle the cargo. The ship is now reportedly bound for Cadiz in Spain. The Leimoniz power station is strongly opposed within Spain; it has been the subject of armed attacks by Basque separatists who have the support of the Left opposition and the trade union movement.

**New study challenges efficacy of nuclear energy:** A new study claims that nuclear power is "technically incapable of providing a timely and significant substitute for oil." A 50% replacement of oil by nuclear power by the year 2000 would require ordering one large power station every 3.5 days. The study, by Amory Lovins of Friends of the Earth, argues in addition that the energy supply problem is "90%" one of heat and portable liquid fuels. Lovins says that if every oil powered station in the OECD in 1975 had been replaced overnight by nuclear stations the fraction of OECD oil which is imported would have only been reduced from 65% to 60%. And at the same time there would be a greatly increased dependency on imported capital and uranium. The maximum role for nuclear power is in providing electricity which is only 10% of all primary energy. Lovins also reviews 19 studies from eight countries and estimates that conservation measures can hold steady or reduce energy needs while maintaining economic growth. Two British studies indicate that growth can triple while total energy demands could be reduced by one half.

"Is Nuclear Power Necessary?" by Amory Lovins. Friends of the Earth, 9 Poland Street, London W1V 3DG.

**Pillinger to appeal case:** David Pillinger, a biochemist made redundant at the Christie Hospital in Manchester (25 January) will take his case to an appeals tribunal. An industrial tribunal ruled against Pillinger last month finding that he had not been unfairly dismissed from his permanent post as Senior Grade Scientist at the Christie because of a lack of funding from the Medical Research Council. The appeal must be based on a point of law with no further consideration of the facts of the case. The question to be raised will "involve the whole three cornered relationship between employer, employee and granting agencies" says Pillinger. In Pillinger's case, a third party has been per-

mitted to exercise the right to hire and fire without giving reasons for its action. According to Pillinger's solicitor the case is "fundamental to the whole concept of unfair dismissal".

**UK6 due for launch this week:** The UK's sixth scientific satellite (above) is due for launch this week aboard a NASA Scout rocket. It is the last of the UK/Ariel series and carries three high energy astrophysics experiments: a cosmic ray detector for studying ultra-heavy cosmic rays; an x-ray telescope system for studying x-ray sources in the range 0.1–2.0 keV; and experiments for observing variable x-ray sources with high time resolution in the range 1.2–50 keV. UK6 will be the last purely British scientific satellite for some time at least although the UK is still negotiating with NASA over the development of a multi-mission refurbishable satellite.

**EEC takes steps to meet energy crisis:** After a delay caused by UK objections to EEC coal buying policy, the Council of Energy Ministers has approved European Community Commission research proposals covering energy saving, geothermal energy, solar energy and coal gasification. The Council has allotted 55 MEUA (£36m) over four years for energy saving projects and 95 MEUA (£63.3m) for research into alternate energy sources. In the UK, the EEC has provided 21 MEUA (£14m) for nine demonstration projects in energy saving. The applications selected under the scheme include three heat recovery projects (in steel making, plaster board manufacture, and in a swimming pool recreation complex) five heat saving manufacturing devices and a monitoring system of energy consumption.

In the meantime, the Union of European Community Industries (UNECI) has issued a report calling for a massive expenditure of 373 billion UA for investment in energy production and an additional 350 BUA for energy prospecting and for research and development. The UNECI report estimates that 650 new coal mines, six natural gas fields, and oil production equivalent to seven Niagras and 600 nuclear power stations will be needed to meet a projected doubling of energy requirements by 2000 AD.

**Skylab falls soon:** The US National Aeronautics and Space Administration announced last week that it was expecting the 85-ton Skylab space station to fall to Earth between 26 June and 9 July, with 2 July as the most probable date. According to the agency, most of the space station, which was launched in 1973 for carrying out research into activities in space, will burn up as it enters the atmosphere. However between 400 and 500 pieces are now expected to reach the surface of the Earth, scattered along a path 4,000 miles long and 100 miles wide.

# Gorleben: winning the battle, losing the war?

**Helmut Hirsch**, coordinator of scientific opposition to West Germany's nuclear reprocessing plans, gives his view of the decision last week not to proceed—for the time being

THOSE of us closely involved in the debate over whether or not to build a nuclear waste disposal centre at Gorleben have, it now seems, been barking up the wrong tree. The Federal Government stated two years ago that one of the conditions for further nuclear expansion in West Germany was what it called the "technical safety and feasibility" of nuclear processing and reprocessing. It was on this basis that the Reactor Safety Commission and the Commission for Radiological Protection expressed their opinion that the Gorleben centre was feasible. It was also on this basis that 20 international scientists, working in the Gorleben International Review, produced a 2,200 page report arguing that it was not. The matter was discussed at the controversial hearings in Hanover which ended on 3 April.

Now, it seems, we were all wrong. Because on 16 May Minister-President Albrecht of Lower Saxony revealed to the astonished German public that he was not worried about Gorleben's "technical safety and feasibility". His chief concern, he said, was its political feasibility. He turned the project down because of political, not technical, opposition.

Albrecht was well aware of the massive opposition to the centre; during the hearings, more than 100,000 people demonstrated in Hanover. He made quite clear in his speech on 16 May that he considered the roots of this opposition were wholly irrational but he decided he would not ram nuclear power down the throats of the ill-informed populace. Or at least he would not do so as long as he was the only one responsible.

Albrecht (who belongs to the CDU) is clearly very irritated about the position adopted by Lower Saxony's Social Democrats. Their leader, Ravens, came out with the conclusion that the Gorleben centre was technically not feasible. Ravens even met Chancellor Schmidt, an outspoken supporter of the Gorleben plan, but Schmidt did not pull Ravens into line. Thus, Albrecht, when announcing his decision, made it clear that he would not take it upon himself to push ahead with reprocessing plans which originated in the Federal Government's (and hence the SPD's) energy strategy but which were opposed by the SPD

in Lower Saxony, who could then profit from their opposition by gaining anti-nuclear voters.

Albrecht also announced the next step: *intermediate* storage of spent fuel elements, probably for up to 40 years, while research into final disposal is to be intensified, covering both post-reprocessing wastes and unprocessed spent fuel elements. However, it is the Gorleben salt dome—and only the Gorleben salt dome—that is to be explored for its suitability for final disposal. If the results are positive, disposal of radioactive wastes will take place there; if not, other sites will then be considered. Clearly the people of Gorleben will have to postpone their victory celebrations.

Local people fear—perhaps with good reason—that this means Gorleben is still the first and only choice for solving West Germany's nuclear waste problems, particularly if pressure mounts for an official decision on a suitable site so that the country's nuclear capacity can expand as fast as possible. They are less than confident that the exploratory drillings at

Minister-President Ernst Albrecht; turned down Gorleben plan for political reasons

Gorleben will be analysed in an unbiased manner, and fear that the salt dome will be proved suitable simply because the nuclear lobby needs it badly.

This concern is shared by Dr Friedrich Mauthe, geologist at Hanover University and one of the participants of the hearings. He says, "So far, nobody has even bothered to define clear criteria stating which drilling results are necessary for a positive judgement. I wouldn't feel too happy if the criteria are tailored after the drillings have been completed".

The procedure envisaged by Albrecht goes right against the conclusions of the Gorleben International Review, whose report emphasised that a broad investigation at several sites would be necessary before any site was singled out. The review expressed doubts about the Gorleben salt dome as well as the suitability of salt as a medium in general. The GIR proposed

detailed and timely investigations of other geologic formations. But at the hearings, Albrecht flatly refused to discuss the Gorleben salt dome.

Albrecht has avoided the question of where to site the intermediate storage facilities. This is another worry for the people of the Landkreis Lüchow-Dannenberg, to which Gorleben belongs. They might yet have to put up with storage ponds. The siting of these at Gorleben would further suggest that the nuclear industry still wants to proceed with the original proposal, with some modifications, and use step-by-step tactics to avoid major conflicts. Considering the determination with which the Federal Government has pushed reprocessing up to now, these suspicions may not be completely unfounded.

Given the uncertainty and political manoeuvring, who can blame the people of Lüchow-Dannenberg if they take things into their own hands? On 10 May, 600 local inhabitants walked into a closed meeting of local politicians discussing the Gorleben issue at Hitzacker, frustrated with the attitude of their representatives, many of whom still have not made up their minds. One farmer shouted: "We do not want the plant, and we do not like it better if it comes step by step!"

Activists collected more than 20,000 signatures in just over two weeks—in a district with 48,000 inhabitants, including children—and are still working to complete their list. The official farmers' union has come out with a clear "no" against nuclear facilities. The resistance is strengthened by the fact that test drilling has been going on at the site more or less continuously for the past two months. The latest news was that drillings had revealed a layer of peat 50–70 m below the surface. This is not unusual over a salt dome, but it indicates that the ground is not suitable for large concrete buildings.

The people of Lüchow-Dannenberg were not surprised by Albrecht's decision. Marianne Fritzen, one of the leaders of the local opposition says: "Albrecht is very cautious, but it is clear to me that he is still in favour of the reprocessing plant." However, many opponents of the project feel that at least a battle has been won. Time has been gained which can be used for a national debate on the issue which really ought to have been paramount: the desirability of reprocessing, and of further use of nuclear energy in general, which has been tacitly assumed by German politicians right from the start. □

*"I decided to learn from them": Dr Oku Ampofo (right), director of the Centre for Scientific Research into Plant Medicine, and one of his herbalists*

## When the scientist meets the medicine men

Joseph Hanlon reports from Africa on the increasing respectability of 'primitive' herbal healing

RESEARCH into medicinal plants is now a high priority in Ghana, and it typifies the issues in science there because it is essentially local and yet, at the same time, tied to the developed world.

Herbal medicine researchers use sophisticated analytical chemistry techniques, collaborate with laboratories all over the world and publish in prestige western journals. Yet they rely on the knowledge of traditional healers to solve problems of tropical medicine which have been ignored by a medical science dominated by the developed countries. Herbal medicine conjures up images of witch doctors and 'primitive' cures. In fact, western drugs came almost entirely from plant and fungus extracts until the 1930s. And many drugs, particularly contraceptive pills, still do.

Plant medicine is still the norm in most of the world, and is not being swept aside by synthetic drugs. One reason is that medicinal plants work. Analysis shows they contain many compounds already familiar to pharmaceutical chemists and do have the antibiotic and other properties claimed for them. Indeed, some work for ailments which cannot be effectively treated by modern "scientific" drugs. Herpes zoster (shingles) is an example.

This point has not been lost on multinational pharmaceutical companies. Faced with spiralling research costs, they are paying more attention to traditional medicines and Third World research. Which leads to the sharpest

contradiction for Ghanaian scientists. They are dependent on high technology only available in European and US labs, and collaboration with those labs is crucial. Yet that means the drug companies are likely to get their hands on the results first. Some scientists fear that new drugs discovered in Ghana and other developing countries will be patented by the multinationals and then sold back to developing countries at high prices. The Organisation of African Unity (OAU) has gone so far as to urge secrecy in herbal medicine research to prevent just this.

Publicity about Chinese traditional medicine systems—both acupuncture and herbal—gave traditional healing international respectability, and plant medicine is now being promoted by the World Health Organisation. Before WHO gave its blessing, however, Ghanaian scientists had already turned to this field.

The Faculty of Pharmacy at the University of Science and Technology (UST) in Kumasi has for several years worked primarily on plant medicines. A number of scientists at the University of Ghana and Korle Bu Hospital are also working in this field. Ghana's Centre for Scientific Research into Plant Medicine, founded four years ago, is one of four centres with official OAU backing.

The centre's founder and director is Dr Oku Ampofo. He qualified at Edinburgh in 1939 and returned to his home town, Mampong-Akwapim (now the

site of the centre). "The war was on, and there were no medicines to be had. There were some old people in the district who were treating patients very effectively with herbal medicines. I saw that some of these things worked. Take the case of a woman bleeding after childbirth. In those days, we were far from any hospital to deal with such an emergency. But they had wonderful herbs for post-partum haemorrhage. So I decided to learn from them." Over the years, he studied with a variety of herbalists and compiled a list of more than 300 remedies.

The Ghana government is spending more than £1 million building the new centre, which will have a staff of 20 scientists. Although the building is several years from completion, two scientists have already been hired and sent abroad for further training.

The centre will also contain a clinic both to treat local people and as a research base. The clinic is already operating in temporary buildings. Three doctors and three herbalists work together, treating patients and keeping careful records. One pilot study has already found several herbs that are as effective as the anti-diabetic drug chloropropamide. The centre has its own arboretum to grow useful local plants and it has just been granted a part of a forest reserve in the Accra Plain where it can grow savannah plants from northern Ghana.

The first research step is always to identify as many active compounds as possible. If one is found with a structure akin to a known pharmacologically active substance, then it explains

how the medicine works, and also serves as proof to doubting Western trained doctors who continue to resist plant medicine. Indeed, some of the chemists I spoke to considered their most important role to be convincing doctors that science has an explanation for these herbs. Pharmaceutical chemists are happiest working with compounds close to those they know and understand.

One of Dr Ampofo's plants now being tested at UST is *Cryptolepis sanguinolenta*, which is sold in the local markets, soaked in water and drunk as an anti-malaria drug. It contains a compound very similar to quinoline.

The same plant is also used by herbalists to reduce fever and to cure urinary infections. Microbial tests show that it is a broad spectrum antibiotic, though none of the compounds isolated so far is a known antibiotic. This is an increasingly common occurrence and has led scientists to catalogue the plants in their traditional form, so they can be sold in shops and used by doctors and herbalists who are not familiar with them. Many of the plants are quite common. Using them directly, instead of waiting for compounds to be analysed, synthesised, and converted to tablet form, makes them widely available much more quickly. The Pharmaceutical Society of Ghana now has a policy that where the scientific basis of a remedy can be shown, and where toxicity tests have been conducted, pharmacists should prepare dosages of the crude plant, rather than attempting extracts. Skin ointments, worm expellers and purgatives are now on the market.

## Testing for safety and side effects

But this, too, has its problems. Plants vary widely according to soil and the time of year (and sometimes even the time of day) when they are picked. Some plants can be highly toxic at certain times of the year and not at others. The herbalists know their local plants well, but this doesn't help those without specialist knowledge. Storage also remains a problem. And the method of preparation is often not precise: "Put a little bit into water"—but how much? Dr Ampofo, through his clinical tests, and the UST scientists, by attempting to find the active compounds, are trying to standardise doses.

Traditional medicines, too, have their side effects and some safety testing seems called for. Dr Ampofo notes that "experienced herbalists will warn you that the plant may have a side effect and if it does, to take another preparation to counter it". Also, "most tropical plants contain poisonous alkaloids. In some cases, if one plant is

used for a treatment, then another must be taken as well to eliminate the toxic effect. *Elaeophorbia drupifera* is useful for guinea worm. The herbalist taps the juice and mixes it with palm nut oil, which renders it non-toxic. Otherwise it is poisonous—you purge yourself to death. I know of one herbalist who has an excellent plant for rheumatism, coroinanthe pacchyceras. But it only works in an alcoholic medium—pound it and put dessert-spoonfuls of powder in 20 ounces of gin. Then take one teaspoonful after each meal. If you boil it up instead, it will put you to sleep for two days."

Traditional healers have been ridiculed in the West—and by western-trained Ghanaians—because of the continued failure to find "scientific" justification for their claims. The Ghanaians argue that western scientists are so confident of their own methods that they are unwilling to listen to anyone from a developing country, despite the hundreds of years of careful study of plant medicine by the herbalists. Many Ghanaians consider Western science too reductionist, constantly trying to find a single extract that can be synthesised and put into tablet form. "I don't think the western world knows how fully to analyse a plant yet. There are certain enzymes we know little about and cannot isolate, but which seem to do good work. In any case, isolation of a single compound cannot be the be-all-and-end-all—it may be a synergistic action in the plant that is doing the healing," Ampofo argues.

He criticises scientists who "follow a routine method of analysing all plants; without knowing anything about what they do clinically. They take a long time and then say it's no good. But if you know that plant A stops bleeding, you straight away look for coagulant effects. You don't just go through to get a long list of formulae."

Another reason to listen to herbalists is to find out the method of preparation. "I found a plant which is extremely good for infectious hepatitis —*Bombas boboperzenze*. You cut the bark to pieces, put it in cold water, and put it in the sun for half a day before drinking. I gave it to a professor and he worked on it for a couple of months and then said he couldn't make head or tail of it. I found out that he had boiled it. If the herbalist tells you to do a preparation in a certain way, it doesn't matter if you are a PhD, you must still follow it exactly."

This new scientific approach has already led to promising research on plants for hypertension a problem in village Africa as much as urban England), guinea worm, skin infections, and many other conditions. By looking in their own gardens, Ghanaian scientists have been able to do research

that could not be done elsewhere. They have staked out an area of scientific research and produced world class results which are being published in the top medical and pharmacological journals.

But the going is not easy. Modern analytical chemistry requires sophisticated equipment that Ghana cannot afford. Advanced drug research today is beyond the means of Ghanaian universities. For example, Dr Ivan Addae-Mensahe, a Ghana University chemist, has isolated an amide alkaloid, wisanine, from *Piper guineense*, the Ashanti pepper. The roots and seeds of this plant are used for a wide variety of conditions, including venereal diseases, mumps, and intestinal disorders. It is also used as a sedative. One alkaloid of the plant, nitidine, has been shown to lower blood pressure, so there is considerable interest in the plant as an anti-hypertensive.

## Can Ghana keep the drug companies at bay?

But Addae-Mensahe could only do part of the work. "With my own equipment, I could isolate the compound and tell if it was pure. I could tell the class of compound, its functional groups, and that the structure was close to something I knew. But I needed mass spectrometry and nuclear magnetic resonance—which I didn't have—to tell the detailed structure." His papers on wisanine cite laboratories in Freiburg, London and Cambridge for analytical work. Other work has been done in Australia and Chicago. Much of the work was done as favours by other scientists—his adviser at Cambridge, a scientist he met in Nigeria, and even a contact made by his brother who studied in Germany. The anti-bacteria properties of wisanine were discovered in Germany; its effects on hypertension are being assessed in the US.

Similarly, discovering that *Cryptolepis sanguinolenta* contained a quinoline-like compound was beyond the capability of UST. They had to rely on friends and their own students in universities in Pittsburgh, Bradford and Upsala. The next step is to conduct tests on monkeys, but Ghana has no facilities. As the multinational pharmaceutical companies are now concerned about the rise of strains of malaria resistant to present drugs, they may take over the work.

Where does this leave the Ghanaian scientists? They are concerned that scientific knowledge is far from universal when patents and profits are concerned. Are they, like the cousins on the farms and in the mines, merely supplying raw materials for the multinationals in the developed world? □

# Another cancer scare . . . or is it hypochondria?

WHERE will the search for environmental carcinogens end? A recent article (Commoner, Vithayathil, Dolora, Nair, Madyastha, Cuca, *Science* **201**, 913; 1978) implicates extract of cooked hamburgers; another, (Bruyninckx, Mason, Morse, *Nature* **274**, 606; 1978) oxygen at physiological concentrations. Both were found to be mutagens in the Ames test. Mutagenicity in this case is usually, though not always, associated with carcinogenicity in mammals.

Commoner *et al.* found that ground beef cooked in a home hamburger cooking appliance contained a substance that induced mutations (reversion from histidine dependence to histidine independence) in some strains of *Salmonella typhimurium*. In the *Science* article the authors are properly cautious: "If . . . these mutagens—once purified and tested on laboratory animals—are found to be carcinogens, their apparent concentration in some foods may represent an appreciable risk to certain populations." But the media were less restrained: these cautious claims were blown up in the United States into the Great Hamburger Scare of Fall 1978. Professor Commoner was widely quoted in the press and on TV, and MacDonald hamburgers' stock prospects were re-examined by alert Wall Street analysts.

The Bruyninckx *et al.* findings are even more startling. It has been known for 25 years that hyperbaric oxygen is a mutagen—but mammals are generally not exposed to hyperbaric oxygen. Bruyninckx found that exposure of certain mutants of *S. typhimurium* to 5% O<sub>2</sub>-5% CO<sub>2</sub>-90% N<sub>2</sub> induced as much as a fiftyfold increase in reversion to histidine independence compared to controls kept under anaerobic conditions. In speculating on the significance of their findings, Bruyninckx *et al.* say, "According to Fridovich oxygen toxicity is normally held in check by a balance among rates of formation and destruction of reactive forms of oxygen. This may mean that oxygen mutagenicity is improbable, but not impossible, in normal aerobic mammalian cells; but higher rates of formation of reactive forms of oxygen or lower rates of their destruction . . . could lead to significant rates of mutagenesis along with the molecular pathologies arising from mutation." Thus Bruyninckx *et al.* do not quite say that oxygen, in the form of the O<sub>2</sub><sup>-</sup> radical, may be implicated in carcinogenesis—but others, notably J. Totter, former Director of the Division of Biology and Medicine of the US Atomic Energy Commission, have suggested just this.

Alvin M. Weinberg, director of the Institute for Energy Analysis, turns his attention to the carcinogenicity of oxygen

If oxygen is dangerous, we'll have to stop breathing . . .

These two findings suggest to me that our entire approach to cleansing our environment of carcinogens may be bankrupted by further investigation. Today's environmentalism assumes that environmental agents that do harm, particularly those that cause cancer, are important causes of cancer compared to the natural environment, and also are removable. But these two doctrines have already been shaken by such findings as the presence of nitrosamines in experimental animals fed a normal diet; or for that matter, the existence of the radiation background, not to say of sunlight itself. Professor Commoner's hamburgers are almost unavoidable (though his directions for cooking mutagenic hamburgers may reduce even this exposure). But I would defy even the most ingenious environmental regulatory agency to legislate acceptable levels of oxygen!

Obviously we must get a better idea of how much cancer is attributable to agents that are in principle removable. The oft-quoted assertion that as much as 80% of cancer is caused by environmental agents that are, at least by implication, avoidable, rests on evidence that can hardly be considered compelling, a point recently stressed by Peto (*Nature* **277**, 428; 1979). To be sure, cancer maps show large fluctuations in incidence of specific cancers in different locations; but the fluctuations are much smaller if all cancers in one location are compared with all cancers in another location.

So far regulatory agencies have not raised seriously the question of how much a known carcinogen can add to the unavoidable risk of cancer. If, for example, it turned out that an all-pervasive environmental agent such as oxygen is importantly implicated in cancer, then we may be attacking the one-tenth of the iceberg that shows (the avoidable carcinogens), but ignoring the nine-tenths that is submerged (the unavoidable carcinogens). I offer this speculation to bring home the great difficulties our regulatory agencies face in trying to legislate acceptable levels of exposure.

I should think that before they outlaw MacDonald's hamburgers, or for that matter, before scientists call for a total ban on this or that carcinogen, we await further clarification of the role of all-pervasive agents such as oxygen in the etiology of cancer. We need more scientific understanding much more than we need additional regulation that is based on imperfect and fragmentary evidence.

Where does the scientist's responsibility lie—in publicising the possibility that a commonly used substance might be a carcinogen (Chicken Little), or in withholding publication until he can really assess the risk, say, compared to other carcinogens (Dr Pangloss)? Chicken Little adds to the public's growing environmental hypochondria; Dr Pangloss conceivably might fail to alert the public to a potential danger. Until now Chicken Little has been in fashion, but I hope the pendulum will swing toward Dr Pangloss. The public ought to require of scientific Chicken Littles the same norms of conduct that science itself has imposed: cautious, provable scientific assertions, and a minimum of appeals to the unrefereed public press.

If such an attitude leads to more Panglossism so be it: people will never stop eating hamburgers, let alone reduce their oxygen uptake, no matter what our scientific Chicken Littles and our regulators urge. □

## Decaying charm

from D. J. Miller

THE charmed particles are proving a great deal harder to study than the strange particles were. Both the charm quantum number and the strangeness number are conserved by the strong and electromagnetic interactions. This means that charmed or strange particles must undergo weak decays whose rate is determined by two factors; the weak-interaction coupling constant  $G_F$  and the density of allowed final states—the phase-space available. By a happy chance the characteristic lifetimes of strange-particle decays are around  $10^{-11}$  s, so for a particle travelling close to the velocity of light the decay-lengths are around a centimetre or more. This is ideal for bubble-chamber work, where the resolution is approximately half a millimetre, and a wealth of precise data now exists on the lifetime and decay schemes of all the basic strange states. Even the elusive  $\Omega^-$  hyperons are now being studied by the hundred.

But although charmed-particle decay processes are also governed by  $G_F$ , the charmed particles are much heavier than strange particles. This leads to a much greater density of allowed final states for each decay-mode and the predicted lifetime drops to the region of  $10^{-13}$  s, giving decay-lengths of a few hundred micrometres; too short for any normal bubble-chamber to observe. In fact, it is quite difficult even to produce charmed particles in a bubble chamber. Most of our knowledge of them comes from the  $e^+e^-$  colliding-beam machines where  $D$ ,  $D^*$  and other charmed states form a significant part of the total rate, once the charm threshold is passed at about 3.8 GeV

(see *News and Views* 269, 286; 1977). Yet such machines have even worse spatial resolution than a bubble chamber, so the presence of the charmed particles is deduced from observation of their decay products with no hope of measuring the decay-lengths of the parent particles. Nuclear emulsions are, so far, the only detectors which offer a chance to see charmed particle tracks. A lone candidate was reported 3 years ago by an international collaboration, using a stack exposed at Fermilab near Chicago (Burhop *et al.* *Phys. Rev. Lett.* **65B**, 299; 1976). Now a continuation of the same collaboration has reported three new events (Angelini *et al.* *Phys. Rev. Lett.* **80B**, 428; 1979; and Ankara, Brussels, CERN+University College Dublin, University College London, Open University, Pisa, Rome, Turin collaboration preprint, to be published) seen in a stack which was placed just in front of the BEBC hydrogen bubble chamber in the CERN SPS neutrino beam. A few percent of charged current neutrino events are known to give charmed particles in the final state. Without the information from the bubble chamber, and its associated muon detector to establish the charged current, it would take hundreds of man-years to scan a large emulsion stack for a useful number of these events. By spotting likely events in the bubble chamber pictures and extrapolating the tracks back to the emulsion it has been possible to find 101 neutrino interactions in emulsion in less than 2 years. The bubble chamber also gives an opportunity to measure the momenta of tracks leaving the

emulsion and even in some cases to identify the kind of particle which produced a particular track. But the emulsion gives the vital information—charmed tracks are indeed a few hundred micrometres long. Unfortunately, for three of the four events reported so far, the information on the momenta and identities of the secondary particles from the charmed decay has not been good enough to allow the masses and momenta of the charmed particles to be established. There is, however, one event in which a strong case can be made that the decaying particle is the charmed baryon  $\Lambda_c^+$  and, if that is assumed, the momentum can be estimated with some precision. The two figures show tracks from this event. In the emulsion (Fig. 1) a single lightly ionised track travels from the neutrino interaction-star on the left of the picture and splits up into three light tracks after 354  $\mu$ m. These particles all give corresponding tracks in the bubble-chamber picture (Fig. 2), marked a, b and c in the figure. In particular, track c makes an elastic scatter from a hydrogen nucleus in the bubble chamber (see arrow on figure). It has been possible to fit this interaction and identify track c with a high confidence-level, as a proton track. Track a does not match quite as well as the other two with its counterpart in the emulsion—it may have scattered slightly in the steel wall of the bubble chamber.

Ionisation measurements in the emulsion, together with the curvature of the tracks in the bubble chamber, indicate that track a is most probably due to a  $K^-$  and track b to a  $\pi^+$ .

Fig. 1

Fig. 2

Taking the best information on all three tracks the event is consistent with production of a hyperon of mass  $2.3 \text{ GeV}/c^2$  and momentum  $3.74 \text{ GeV}/c$ . It decays to  $K^-\pi^+p$  after living  $7.2 \times 10^{-13} \text{ s}$ . The other three events have similar decay lengths so their decay times must be in the same region.

Because the charmed quark is thought to be much heavier than the everyday  $u$  and  $d$  quarks or the strange  $s$  quark, when a charmed particle decays the process should be simpler than in strange particle decays. To predict the rate for a particular strange decay requires a detailed discussion of the dynamics of two or three-body final states, with special enhancements and even *ad hoc* selection rules. Charm decays, in the current weak interaction theory, should have about the same rate whether the charmed quark is in a charmed baryon or in a charmed meson. The energy released is much bigger than the variations in mass between baryons and mesons, so the quark can decay at its own pace and the final state is rearranged over a comparatively long period afterwards. (This is the same sort of 'parton' argument that is used to explain the deep inelastic interactions of electrons or neutrinos with quarks, quark-pair production in  $e^+e^-$  annihilation or large transverse-momentum jet production in proton-proton collisions). It is thought likely, in view of the number of  $K\pi\pi$  events seen in searches for charm in bubble chamber neutrino events (Baltay *et al.* Columbia-Brookhaven collaboration; *Proceedings of the Oxford Neutrino Conference 1979*, page 198, published by the Rutherford Laboratory) that most of the charmed particles produced by

neutrino interactions are D mesons, not  $\Lambda_c$  hyperons. Some of the other emulsion events are consistent with many-body D decays, so it is encouraging for theorists that the apparent survival times of all events are similar to that of the  $\Lambda_c$  event.

This event is also encouraging on a more fundamental level. As soon as charm was taken seriously it was possible to predict the whole  $SU(4)$  spectrum of charmed mesons and baryons. In the past 5 years many dynamical effects have been explained by the existence of charm, but few members of the charmed spectrum have been firmly established. The  $\Lambda_c$  has been reported before (see for example Cnops *et al.* *Phys. Rev. Lett.* **42**, 197; 1979 and references therein) but each piece of evidence was slender. A well reconstructed  $\Lambda_c$  track is a considerable advance. □

## Bacterial defences against penicillins

from a Correspondent

WE cannot always take a detached view about the outcome of conflicts between one form of life and another. We seek to kill pathogenic bacteria with antibacterial agents—but this onslaught may be resisted by the bacteria, which may produce (or contain) an enzyme that destroys the drug. Penicillins and cephalosporins are among the most effective antibacterial agents and they owe their activity to the presence of the four-membered  $\beta$ -lactam ring. Enzymes that catalyse the hydrolysis of the  $\beta$ -lactam ring—and consequently inactivate the drugs—are called  $\beta$ -lactamases. The increasingly wide occurrence of bacterial  $\beta$ -lactamases has become a source of concern to clini-

cians and a challenge to chemists and biologists. Hence inactivators of  $\beta$ -lactamases are not only tools for enzymologists, they are also potential chemotherapeutic agents. It was against this background that a workshop\* was held recently at the University of Newcastle upon Tyne to discuss the biochemistry of bacterial  $\beta$ -lactamases. There have been significant advances in our understanding of  $\beta$ -lactamase action since the first workshop was held, 4 years ago (see *News and Views* **255**, 526; 1975). Moreover, then we had no effective inactivators of these enzymes; now we have several.

Information about structure, although often laboriously acquired, is particularly significant and enduring. All our knowledge of amino acid sequences in  $\beta$ -lactamases has come from the laboratory of R.P. Ambler (University of Edinburgh) recently—and dramatically—complemented by the work on the nucleotide sequence of a plasmid that encodes a  $\beta$ -lactamase (J. G. Sutcliffe, Harvard University). It is noteworthy that the  $\beta$ -lactamases from *Staphylococcus aureus*, *Bacillus licheniformis*, *Bacillus cereus* ( $\beta$ -lactamase I) and *Escherichia coli* have amino acid sequences that are sufficiently similar to show that they must be classed as homologous proteins. We may thus expect that one mechanism will apply to all these enzymes. By way of contrast, Ambler reported that  $\beta$ -lactamase II from *B. cereus* had so far shown no sequence similarity to the other  $\beta$ -lactamases, and he concluded that this is a strong candidate for an analogous (as opposed to a homologous) enzyme. Moreover,  $\beta$ -lactamase II is exceptional in requiring Zn (II) for activity. S. G. Waley (University of Oxford) (reporting on work carried out in collaboration with H. A. O. Hill and E. P. Abraham) described spectroscopic evidence that the ligands to the essential metal atom were three histidine residues and the enzyme's sole thiol group.

The intermediates in the pathway of synthesis and export of the extracellular  $\beta$ -lactamase of *B. licheniformis* now include species of molecular weight 35,000, 33,000 and 31,000 (J. Lampen, Rutgers University, New Jersey). Structural characterisation of these interesting intermediates is, however, not yet complete.

Information about the three-dimensional structure of  $\beta$ -lactamases is eagerly awaited; J. R. Knox (University of Connecticut) described his progress, both on the  $\beta$ -lactamase from *E. coli*, and on the transpeptidase from *Streptomyces* R 61; which of the structures being studied in several labora-

\*Held on 27–29 April and organised by Professor R. H. Pain and Dr R. Virden (University of Newcastle-upon-Tyne). The workshop was supported by Glaxo Research Ltd.

David J. Miller is in the Department of Physics, University College, London.

tories will be solved first remains to be seen.

Turning from structure to mechanism, one of the highlights of the meeting was J. R. Knowles's (Harvard University) presentation of the first good evidence for an acyl-enzyme intermediate in the enzymic reaction. The hydrolysis of a 7- $\alpha$ -methoxycephem (cefoxitin) by the RTEM  $\beta$ -lactamase from *E. coli* proceeds slowly enough for an intermediate to be isolated at 0 °C; the low molecular weight moiety is covalently bound. When the reaction in solution was monitored by Fourier-transform infrared spectroscopy, the intermediate showed a band at 1753  $\text{cm}^{-1}$ . This is consistent with the intermediate's being an ester, and this, in turn, implicates a serine or threonine residue in the enzyme's action. The importance of serine in  $\beta$ -lactamase I follows from the work of P. G. Sammes (University of Leeds) and Waley who have found that the amino acid residue labelled by an inactivator is serine 44 (serine 70 in Ambler's method of numbering). This is a conserved residue in the sequences referred to above. These results, and those of Knowles, taken together suggest that  $\beta$ -lactamases may now be regarded as 'serine enzymes'. The inactivator used by Sammes and Waley (which was independently discovered by R. S. Pratt, Wesleyan University, Connecticut) was 6- $\beta$ -bromopenicillanic acid, and the labelled enzyme is thought to be a dihydrothiazine. A. F. Coulson (University of Edinburgh) used the sulphone of 6- $\alpha$ -chloropenicillanic acid to inactivate the  $\beta$ -lactamase from *Staphylococcus aureus*: the site labelled is close to (or identical with) that referred to above. The chemistry of the inactivation by these reagents entails acylation followed by fragmentation, according to the views of those using these inactivators, but the structures postulated have yet to be firmly established.

The detailed studies by R. H. Pain and R. Virden (University of Newcastle-upon-Tyne) on the conformation and activity of the  $\beta$ -lactamase from *S. aureus* have led to a three-domain model, with the active site at the interface of two domains. This protein is one of the few for which a partially unfolded form has been well characterised.

Methods of obtaining information about the practical importance of  $\beta$ -lactamases in protecting bacteria against the antibiotics were discussed by G. W. Ross (Glaxo Research, Greenford) and by M. H. Richmond (University of Bristol). Mutants of certain strains of *E. coli* have been obtained lacking the barrier to inflow of antibiotic, and these are helping to throw light on the least-understood

aspects of  $\beta$ -lactamases. These concern the relative positions (in Gram-negative bacteria) of the  $\beta$ -lactamase and the target that the antibiotic interacts with.

As usual, much remains to be done, but significant advances have at last been made in the understanding of these efficient but unwelcome enzymes.

## High energy jets

from M. G. Albrow

In the past few years high energy physicists have progressed beyond the study of the interactions of the strongly interacting particles, the hadrons, to the study of the interactions of their constituents. All known and postulated observable 'elementary particles' fall into three classes (see the review article by Mulvey *Nature* **278**, 403; 1979). These are the leptons (electron, muon, tau and neutrinos), supposedly fundamental particles with half a unit of intrinsic angular momentum (spin) which have no strong interaction coupling, the hadrons (proton, neutron, pions, kaons and so on) which interact strongly, and the field bosons (photon, graviton, intermediate vector bosons) which are the quanta of the force fields acting between the leptons and hadrons. It has become universally accepted that the hadrons are not truly elementary particles but are composite objects. They are probably composed of two types of constituent—quarks, which are very similar to the leptons except that they have a non-zero strong charge, and gluons, which are the field bosons or quanta of the strong force. Thus all matter consists of spin  $\frac{1}{2}$ h particles either with no strong charge (leptons) or with a strong charge (quarks) interacting by exchanging field quanta (bosons).

And yet despite extensive attempts to kick a quark or gluon out of a proton and observe it as an isolated entity, none has succeeded. One can set up a collision experiment that should produce a quark, even to the extent of knowing in which direction it should be produced and with what momentum. In that direction one finds not a single particle but a set of several hadrons moving in roughly the same direction, with a total momentum equal to the momentum the quark should have had. It is just as if the quark produced immediately breaks up into more familiar particles. Such a set of hadrons is called a 'jet', with a jet axis defined as the direction of the vector sum of their momenta. Each member particle has a momentum component parallel to the jet axis and a component transverse to that axis. An observed charac-

teristic of jets is that the average parallel component grows linearly with the total jet energy, while the transverse component remains small, a few hundred MeV/c. Consequently as the total jet energy increases, the angles between the member particles decrease and the jets become more collimated. In the highest energy collisions the jets produced become sufficiently distinct that the multi-jet configuration of the resulting particles appears. Even though in a very high energy collision dozens of particles may be created, it is now postulated that they are all members of a small number (typically 2–4) of these jets. That is to say that a small number of axes can be found such that no hadron has a large transverse momentum component to all the axes. If each jet is taken as signifying the direction of a quark or gluon the description of the collision process takes on a remarkable simplicity.

How do these jets appear, in the reference frame in which the total vector momentum of all the particles is zero (the centre-of-mass frame)? In Fig. 1a an electron and a positron collide; they annihilate and all of their energy is converted into hadrons. Typically two colinear jets of hadrons are observed, the axis making an angle  $\theta$  with the collision axis. The angular distribution has a form  $(1 + \cos^2\theta)$ , which is exactly that expected if just two spin  $\frac{1}{2}$ h particles, namely quarks, were produced and then disintegrated into hadrons. Collisions of this type were first seen at SPEAR in Stanford, California in 1975 (Hanson *et al. Phys. Rev. Lett.* **35**, 1609; 1975) and become much more striking at the higher energy now available at DESY in Hamburg (Berger *et al. Phys. Lett.* **78B**, 176; 1978).

In Fig. 1b an electron-proton collision is shown, with the electron emerging intact after suffering a deflection and loss of energy. Again the created hadrons seem to group themselves into a pair of jets which are however not colinear. One of the jets recoils against the deflected electron and its internal structure appears similar to that of the jets produced in  $e^+e^-$  annihilation, suggesting that a quark has been kicked out of the proton and has subsequently disintegrated in the same way. The rest of the hadrons form a second jet pointing along the direction of the incident proton—presumably arising from the remaining proton constituents after one quark has been removed.

A stage further in complexity is the proton-proton collision seen in Fig. 1c. Whenever particles with large transverse momentum relative to the collision axis are observed, they occur in pairs of jets approximately balancing each other in momentum. The natural

M. G. Albrow is at The Rutherford Laboratory.

**Fig. 1** *a-c*: Three classes of high energy particle collisions producing jets of hadrons. The initial state, the inferred primary products and the final state hadrons are shown as momentum vectors.

interpretation is that a pair of constituents (one from each proton) has scattered through a large angle.

From these three types of collision process studied at three quite different types of machine ( $e^+e^-$  colliders at SPEAR and DESY, large accelerators at FNAL and the CERN SPS, and the CERN proton Intersecting Storage Rings (ISR) a unified programme of research has now emerged. The first process (Fig. 1*a*) is the ideal way to study the mechanism by which quarks evolve into hadrons, the second (1*b*) can measure the distribution of quarks inside a proton and the third (1*c*) can study the quark-quark scattering process. This threefold attack on the study of the strong interaction was the subject of a Jet Symposium held last year at the Neils Bohr Institute in Copenhagen (*Physica Scripta* **19**, (2) 1979).

Quite how the emerging quarks turn themselves into hadrons is still something of a mystery. Our present understanding of the strong forces between quarks is based on quantum chromodynamics theory (QCD). In this theory the quark-quark force increases as their separation increases, unlike electromagnetic forces where the reverse is true. It may then take an infinite amount of energy to separate a pair of quarks to macroscopic distances. As quarks separate, the energy contained in the increasingly strong field builds up until it is sufficient to 'polarise the vacuum', resulting in a newly created quark-antiquark pair. This process repeats itself until most of their kinetic energy is spent, and the created quarks and antiquarks arrange themselves into hadrons. Unfortunately it is not yet possible to calculate the details of this complicated process. It is still an open question whether free isolated quarks can be produced in sufficiently high energy collisions—it is conjectured, but not yet proved, that they are permanently confined. In that case we may now be exploring the last rung of the ladder down from atoms through nuclei and elementary particles to their most fundamental constituents. □

## Arabic science at Aleppo

from Subir K. Banerjee

FOR historians of Arabic science an important meeting\* took place in Aleppo, recently. The President of this young university Ahmad Y. Hassan, himself a noted historian of technology, has single-handedly provided the impetus for the creation of the world's first major centre devoted to a comprehensive study of all the Arabic sciences, the Institute for the History of Arabic Science at Aleppo University. The institute is also responsible for the publication of the *Journal for the History of Arabic Science*, the first journal of its kind. The term Arabic Science is used in preference to Islamic Science, perhaps to emphasise the idea that we are dealing here with the history of science (and technology) written in the Arabic language which was the language of rational inquiry in the Occident during the period AD 800–1400.

Why should anyone study Arabic science? Before we in the modern West mumble something about its impact on the European Renaissance it is worth recalling what E. S. Kennedy, one of the doyens of studies in Arabic mathematics and astronomy has said, "There need be no laboring of the concealed notion that the providential function of the Arabs was to preserve Greek science against the time when Western Man should awake from his slumbers of the Dark Ages". Taking this view one step further I would like to say that while intrinsically laudable, it is an extremely parochial and ethnocentric view to emphasise in the study of Arabic science only the role of transmission to the Latin West at the cost of minimising the grandeur and

\*The Second International Symposium for the History of Arabic Science was held on 5–12 April at Aleppo, Syria.

Subir K. Banerjee is Professor of Geophysics and Adjunct Professor, Program in Middle Eastern and Islamic Studies, University of Minnesota, Minneapolis.

breadth of Arabic science as science *per se*. It is a sobering thought that perhaps only 10% of the total Arabic scientific oeuvre is known to have been translated into Hebrew and Latin. The growth, maturity and decline of Arabic science should be studied primarily as the flowering of human mind during a certain era and for the lessons it can offer to all mankind.

The symposium was successful in driving home this broader viewpoint of Arabic science. One interesting contribution in the sessions on the 'Transmission of Arabic science to the Latin West' was Marie Therésé d'Alverny's discovery of the important influence of Arabic cosmology in the 12th century *Dialogus* of Peter Alphonsi. A highlight was A. I. Sabra's talk in the general session on the place of science and medicine in medieval Islamic civilisation. Over the past few years in private conversations and in short articles Sabra has indicated that he is struggling with the problem of decline of Arabic science and at the symposium he was able to state clearly his new approach to the discussion of this problem: he is concentrating on the careers of the individual scientists of this age, their training, flourishing and activity later in life. In the topical sessions I attended it was most exciting to hear of G. Saliba's identification of the Damascene astronomer al-'Urdi (13th century) as the original author of the planetary model which constituted an alternative to the Ptolemaic model and that 'Urdi's model appears to have been adopted by the more well-known Qutb ad-Din ash-Shirazi. Other interesting new information selected at random is that the Arabs had a magnetic compass for scientific use as early as 13th century and that a 14th century Aleppan astronomer, as-Sarraaj, had invented an exceedingly complex universal astrolabe which, additionally, had the equivalent of a slide rule on its back for complex calculations in spherical astronomy, the trisection of an arbitrary angle and the nature of the lunar surface. □

## Timing time

from P. C. W. Davies

IT has been predicted for 60 years that time runs faster in space than on Earth. Now the prediction has been verified by a direct experiment in which a high-precision clock—an atomic hydrogen maser—was flown into space on board a spacecraft. In a recent issue of *General Relativity and Gravitation*, two Harvard astrophysicists, R. F. C. Vessot and M. W. Levine, report the preliminary results of the experiment,

which took place over the Eastern United States in June 1976.

The effect being verified is caused by the action of gravity on time, which forces clocks (and all natural activity) to run more slowly in the Earth's gravitational field. At high altitudes where gravity is lower clocks speed up. The phenomenon follows directly from the assumption that energy has weight, through a simple argument. When a body is lifted it acquires some extra energy by virtue of the work expended to elevate it. If the energy that drives a clock (for example, elastic energy of a spring or vibrational energy of a balance wheel) also has weight, then additional work must be performed to lift it: crudely speaking, a ticking clock is heavier than an inert one. The extra work expended appears as enhanced internal energy which thereby induces the clock to run more energetically, that is, faster.

The time distortion effect is a completely general one and is really a property of time itself, not merely a mechanical shortcoming of clocks. It is a central prediction of Einstein's general theory of relativity because weighing energy amounts to checking the so-called equivalence principle—that gravity is locally indistinguishable from an acceleration. The effect is minute in the case of the Earth, but in certain astronomical objects such as black holes, it can become enormous.

In 1959 a modest precursor of the Vessot-Levine experiment was performed at Harvard University by R. V. Pound and G. A. Rebka. Very finely tuned gamma rays produced using the Mössbauer effect were shot vertically up a tower 22½ metres high and their frequency at the top compared with that at the base. The tiny shift of only a few parts in  $10^{15}$  could be detected by compensating for it with the Doppler effect, which shifts the frequency of radiation from moving sources. The spacecraft experiment improves on this by probing much greater changes in the Earth's gravity than from the bottom to the top of a tower. The payload was projected 10,000 km into space atop a Scout D rocket launched from Wallops Island, Virginia. At this altitude the time distortion is as much as five parts in  $10^{10}$ , well within the detection capabilities of modern atomic hydrogen masers.

The principle of the experiment was simply to compare the beats of the maser in space with two standard Earthbound masers. In practice there are great complexities involved because other more prosaic effects, such as ionospheric disturbances and Doppler shifting due to the spacecraft motion,

*P. C. W. Davies is a Lecturer in the Department of Applied Mathematics, King's College, London.*

## More news on SS 433

*from A. C. Fabian*

THE moving emission lines of SS 433 were one of the most exciting astronomical discoveries last year (see *News and Views* 277, 267; 1979). Since the object became visible in the night sky this year many telescopes have been following its behaviour. At the Spring meeting of the American Physical Society in Washington, DC, Bruce Margon (University of California, Los Angeles) reported that the enormous variations in line position are due to the Doppler effect. He and colleagues at the University of California and elsewhere have been prominent in observing and unravelling this bizarre spectrum, and find that all emission lines visible in their spectrographs are split into three components. Those either side of the component at rest wavelength move in the opposite sense and are displaced by an equivalent velocity which varies up to  $+52,000 \text{ km s}^{-1}$  and  $-30,000 \text{ km s}^{-1}$ . The asymmetry is likely to be due to the transverse Doppler effect in emitting matter that is travelling (probably in two diametrically opposite directions) at about  $80,000 \text{ km s}^{-1}$ . The change in velocity represents an acceleration  $\sim 1g$  over several weeks. The overall variation appears to recur on a period of  $160 \pm 3$  days (or some multiple of that). The radial velocity curve passes through a cycle of  $\sim 104 \text{ d}$  which is repeating this year within 2% (including some small but significant variations). The remaining part of the curve should be visible this summer.

*A. C. Fabian is Radcliffe Fellow in Astronomy, Center for Astrophysics, Harvard.*

have first to be taken into account. One vital requirement was to obtain accurate information about the spacecraft trajectory, because the time distortion effect is a function of altitude. The accuracy aimed for is about  $\pm 100 \text{ m}$  in position and  $\pm 6 \text{ cm s}^{-1}$  in velocity near apogee, though the authors admit that as yet substantially larger uncertainties exist. Further data reduction will be undertaken to improve the understanding of the trajectory, especially at low altitudes. On the basis of current data, the clock rate distortion predicted by the general theory of relativity is verified to two parts in  $10^4$ .

The principle of equivalence can be checked in other ways, such as the Dicke-Eötvös experiment, which uses a type of balance at a fixed location on the Earth, and is found to be correct

Margon emphasised that this is the first time definite evidence has been found for large scale matter moving towards us at relativistic speeds—even the Paschen lines can be seen in the visible at maximum blueshift. Simply interpreting the radial velocity curve as due to a binary system leads to the picture of two masses of  $2 \times 10^8 M_{\odot}$  orbiting each other just beyond their respective Schwarzschild radii. Perhaps more plausible would be to consider that the emitting matter lies in two jets which are waving around with a period of 160 days. Radio astronomers find evidence for jets in radio galaxies, and relativistic matter squirting out of a galactic nucleus seems to be necessary in order to explain the superluminal expansion in many of these sources. SS 433 may represent a much scaled down galactic version of one of these nuclei. I currently favour a precessing neutron star as the underlying source of energy—Margon has noted that the inferred matter velocity in SS 433 is close to the velocity of escape from such an object. (As an aside it may be noted that SS 433 could be used by an interstellar civilisation to thrust them up to relativistic speeds!)

SS 433 would be visible in binoculars if its position in the galactic plane did not cause significant dimming of its light. Nevertheless, it is within the grasp of many telescopes and must represent one of the most spectacular objects visible. Special relativity can now be demonstrated at significant fractions of the velocity of light on something more than subatomic particles. The emitting mass in SS 433 exceeds  $10^{24} g$ .

to one part in  $10^{12}$ . If the principle is assumed correct, then the Vessot-Levine experiment can be used instead to check that the velocity of light is independent of direction by comparing the one-way and two-way light travel time from the ground to the spacecraft. In fact, the authors comment that there are a whole range of possibilities opened up by the use of high precision clocks aboard spacecraft.

About 70 years ago Einstein and others developed the theory of relativity by appealing to so-called 'Gedanken' experiments in which observers undergo hypothetical experiences involving gravitational fields and different states of motion, while equipped with measuring rods and clocks. In those days spaceflight and super-accurate technology were merely a dream. Now, less than a century later,

some of these fantasy experiments can actually be performed, and the measuring rods and clocks, albeit in technically unrecognisable form, have become a reality. Vessot and Levine point out other experiments which are feasible with current technology using clocks in space. One of these is the measurement of the Lense-Thirring frame-dragging effect, which is a sort of vortex in space in the vicinity of a rotating massive body. Determination of the magnitude of the effect due to the Sun by orbiting clocks near the solar surface in a drag-free satellite, would enable an accurate measurement to be made of the total angular momentum of the Sun, a quantity which is crucial to our understanding of stellar structure. Another possibility is the detection of very low frequency gravity waves which, when washing through the Solar System, cause long-period fluctuations in clock rates. There is no doubt that as technology improves, more and more of the exceedingly minute, though highly significant distortions of space and time predicted by Einstein's theory will come within the scope of direct experimental verification. □

## Micro-ecology

from N. MacDonald

A RECENT review in *Nature* (Bloom 279, 21; 1979) of immunological aspects of parasitism, discusses the methods adopted by parasites to survive within host cells. A full issue of the *Proceedings of the Royal Society* (B204, 1979—arising from a meeting held last year) has recently been devoted to wider aspects of the cell as a habitat for other cells, covering mutualistic interactions as well as parasitism. The evolutionary implications of early symbionts (cells inhabiting cells) which may have become integrated into the structure of more complex cells (present-day mitochondria and chloroplasts for example), have been widely discussed, and are reviewed by F. J. R. Taylor and by J. M. Whatley *et al.* (These and all subsequent references are to papers in the previous reference). The general topic of the micro-ecology of contemporary symbionts, their mechanisms of adaptation to the intracellular environment, and the regulation of their populations by that environment, is probably less widely known.

Various kinds of association of host cell and symbiont can be arranged in order of increasingly close integration. Most symbionts are segregated by en-

closure in a membrane-lined vacuole. Those that are not can typically not be grown outside the host cell. These are presumably candidates for a process in which they lose their separate identity and merge with the host cell, at any rate in cases where the association is mutually advantageous.

This potential loss of identity is not the only way in which the cell as an environment is vastly different from the physical environments of large-scale ecology. Regulation of the population of the symbiont is necessary lest it grows to the extent of bursting the host cell, as well as for restraining the competition of the symbiont for resources needed by the host. In all cases of stable association in which the symbiont is capable of separate existence, the maximum intracellular growth rate of the symbiont population is less than the maximum extracellular growth rate (D. C. Smith). Some of the regulatory mechanisms (as discussed for example by L. Muscatine and R. R. Pool for intracellular algae) are reminiscent of those encountered in animal ecology, at least in so far as one regards the environment of a particular species as including its predators and competitors. The host cell may expel the symbiont, consume it or starve it by competing for a resource. One radically different mechanism, for which there is now some evidence, is the triggering of mitosis in the symbiont by mitosis of the host.

J. W. Moulder discusses the cell as an extreme environment, explicitly examining the partial analogy with physical extreme environments, such as hot springs or salt lakes. Such environments are characterised by low diversity of the species that inhabit them; frequently there is a single dominant species. This species is likely not only to have adapted to the presence of the primary non-biological limiting factor, such as temperature or salinity, but to have become dependent on it. The limiting factors of a host cell are of a more varied and active nature. The cell can exclude or destroy most potential symbionts, so that a single dominant symbiont, which has managed to evade these defences, is typically present. Some kinds of intracellular parasite possess special techniques to gain access to cell interiors, while others simply allow themselves to be engulfed by macrophages, while contriving to avoid subsequent destruction. Enclosure of the symbiont by a vacuole can be thought of as tempering the severity of the extreme intracellular environment.

To give a final twist to the discussion of this complex and intriguing kind of biological association, M. H. Richmond discusses the bacterial cell as a habitat for extra-chromosomal DNA frag-

ments, such as plasmids, which can specify resistance to antibiotics or the ability to metabolise novel substrates. In this context plasmids can be regarded as molecular symbionts whose effect is to allow the bacteria which carry them to penetrate otherwise inhospitable habitats. □

## A hundred years ago

THE first public act passed by the U.S. Congress during the present session, was one making an appropriation of 200,000 dollars for the construction, under the direction of the Secretary of the Treasury, for the National Board of Health of a vessel provided with suitable refrigerating apparatus, for the purpose of determining the possibility of destroying the yellow fever infection by intense cold. The act first introduced had special reference to the apparatus of Prof. Gamgee, but as passed it is within the power of the Secretary to select any device that will, in the opinion of the National Board of Health, best answer its purpose.

THE *Colonies and India* furnishes some interesting particulars respecting the so-called "vegetable ivory," which is now so much used as a substitute for ivory. The vegetable ivory nut is the produce of a species of palm found wild in South America and Africa. Inside the hard shell is the white kernel, which being softer than ivory and easily carved, as well as readily dyed, and being less brittle than bone, is largely used in making buttons, &c. The unripe fruit consists of a green shell, containing a watery fluid, which, as the nut ripens, gradually thickens until it becomes a pulpy mass, and eventually hardens into solid matter. The water, though bitter to the taste, is wholesome, and often renders invaluable service to travellers, who cannot otherwise obtain water to drink. The tree (*Phytelephas macrocarpa*) on which the fruit grows is unlike an ordinary palm, having little or no stem and drooping downwards, especially when the weak branches are overweighted by the six or seven bunches of nuts, each containing six or seven seeds, inclosed in thick heavy shells and outer sheath, and weighing altogether from 20 to 24 lbs.

EXTRAORDINARY finds of gold have lately occurred in the gold-fields of Dutch and French Guiana and are causing great excitement.

## Virological evidence for the success of the smallpox eradication programme

I. Arita

Smallpox Eradication Unit, World Health Organization, Geneva, Switzerland

*Smallpox has prevailed throughout the populated world during the last four centuries but the World Health Organization's eradication campaign has now apparently interrupted transmission of the disease in the human population. The risk of natural re-introduction of the disease is negligible.*

TEN years ago the worldwide incidence of smallpox was estimated to be about 10 million cases annually but since October 1977, when a case of smallpox was recorded in Somalia, there has been no naturally occurring smallpox reported throughout the world. Hopes that the case in Somalia would be the last instance of smallpox in the world were destroyed by the outbreak of smallpox in Birmingham, UK in August 1978. This caused considerable concern among the scientific community as well as the public because laboratory virus stocks appear to have been the source of infection. Although the focus of attention has been on measures to minimise the potential danger of variola virus stocks in laboratories, it is equally important for the world scientific community to examine whether variola virus has really become extinct in the human population and if so, what future surveillance and research on orthopoxviruses are required to ensure the permanent status of this phenomenon. I attempt in this article to present a summary of scientific data and review these problems.

### The origin of smallpox

Ancient records in China and India imply that smallpox, easily recognised by the descriptions of its typical rash, high death rate and extensive transmissibility, was present in the eastern part of the Asian continent long before the Christian era. There are also records from that time of attempts to immunise susceptible persons with extracts of smallpox lesions (variola).

As man is the sole host of variola virus and no animal reservoir exists, continuous transmission of variola virus in the human population required aggregates of susceptible individuals such as first occurred about 5,000–6,000 yr ago when agricultural development made it possible to support populations of more than 500 living together in one place (F. Fenner, personal communication). The disease apparently spread in all directions from the eastern part of Asia along with population movements due to trade, religious and political conflicts and exploration. The disease first appeared in Asia Minor in the early Christian era and around the same period southern Europe was infected. Smallpox reached Japan in the eighth century, the Americas in the sixteenth century, Siberia in the seventeenth century and Australia in the eighteenth century. Its devastating effect when first introduced into a new population has been well described. The disease probably originated from one place—eastern Asia—roughly 5,000 yr ago and has prevailed over the past four centuries throughout the populated world.

A finding inconsistent with this theory is that Rameses V of Egypt died of an acute disease in 1,100 BC which left pock-like

lesions on his mummified face. Electron microscopic examination of the pock lesions on this mummy might shed light on the diagnosis of the disease and the World Health Organization (WHO) and the Egyptian government are discussing this possibility. If Rameses V's illness was smallpox, this means that smallpox was already present in northern Africa at that time. The Roman, Egyptian, Babylonian, Assyrian and Persian civilisations have left considerable historical records, but there is no evidence indicating a smallpox epidemic in these areas around that time. Two hypotheses can be proposed; the disease may have been introduced from the East (commercial trade between Egypt and Asia was well established as far back as 1,100 BC) and, leaving no recognisable records of a smallpox epidemic, may have died out spontaneously; or, the source of Rameses V's disease could have been the African continent, perhaps Central Africa with which Egypt might have had communications along the River Nile. However, there is no way of determining which hypothesis is correct.

### Prevalence of smallpox

At the end of the eighteenth century, Edward Jenner showed that material extracted from the lesions of cowpox would immunise against smallpox, and could replace variolation. During the following 150 years Jenner's 'vaccine' was gradually accepted by health services all over the world. However, over the years the virus strains used for vaccine production did not remain identical to those used by Jenner. By the 1950s, the existence of an effective vaccine and its coordinated use in vaccination programmes had resulted in the interruption of indigenous smallpox transmission in many countries in the temperate zones. Smallpox was, however, still prevalent in many of the tropical countries of Africa, South America and Asia. One reason for this was that the smallpox vaccine rapidly lost potency when exposed to tropical climates.

In the early 1950s a method of freeze-drying smallpox vaccine, so that it retained its potency for at least 4 weeks at 37°C, was adapted to large-scale production<sup>1</sup>. This freeze-dried vaccine, stable in tropical climates without refrigeration, greatly enhanced the prospects for smallpox eradication.

In 1967 the WHO initiated an intensified global smallpox eradication programme. At that time, smallpox was endemic in 33 countries and cases were reported by 44 countries (Fig. 1). The campaign involved a massive investment of manpower, vaccine, technology and managerial skills. The total cash input from international assistance during the past 12 years is estimated to be about \$100 million. The essential strategy of the

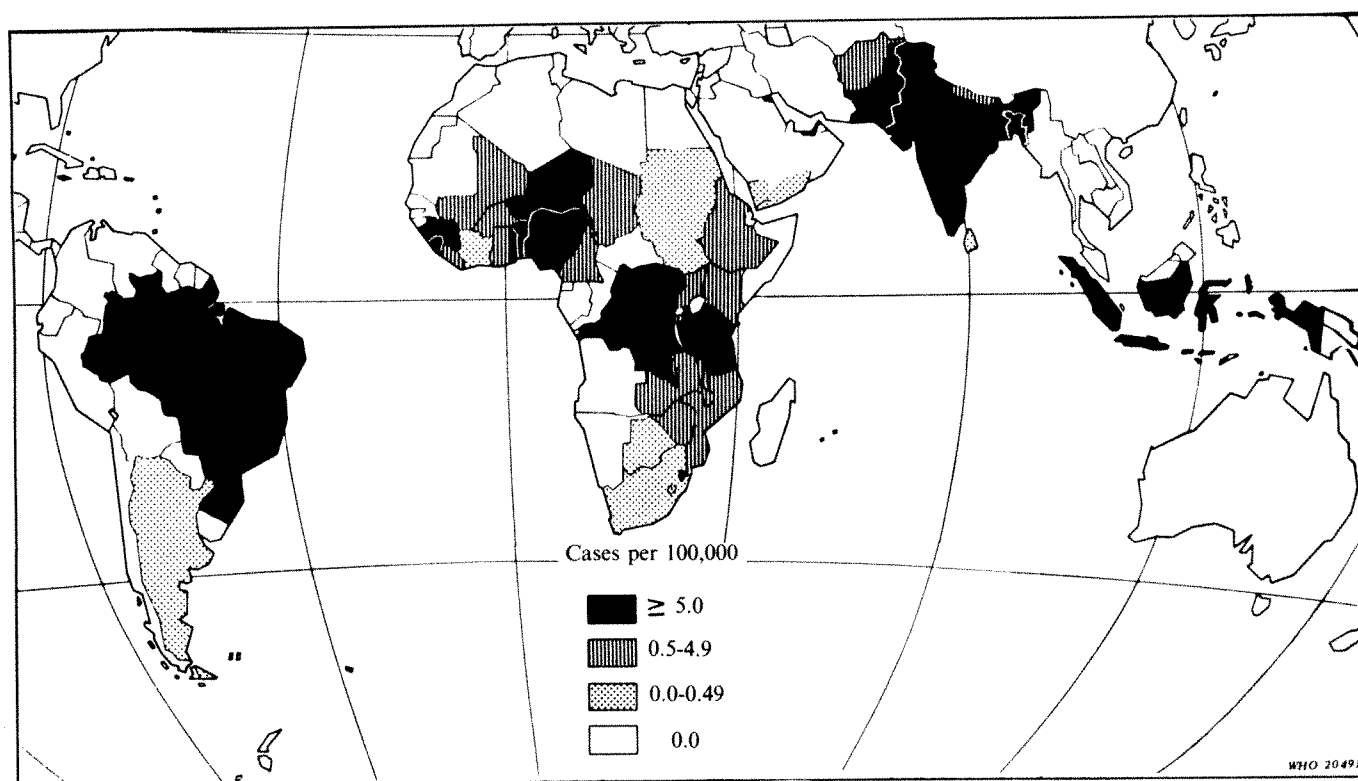

Fig. 1 Smallpox cases per 100,000 inhabitants in 1967.

programme was epidemiological surveillance combined with prompt containment of outbreaks detected<sup>2</sup>.

Among milestones in the progress of the smallpox eradication programme have been the recording of the last cases in South America and West and Central Africa in 1971; in Indonesia in 1972; in southern Africa in 1973 and in the Asian subcontinent in 1975. Since 1976, the endemic foci were confined to the Horn of Africa. The last known case of smallpox of natural origin was detected in Merka town, southern Somalia in October 1977 (Fig. 2).

### Certification of interruption of smallpox transmission

Do any foci of smallpox remain hidden in densely populated slum areas, remote tropical rain forests or isolated deserts? Past suspicions of this had some justification. A pockmark survey in Nigeria in 1971 revealed that the completeness of smallpox case reporting before the campaign began was only 1% in rural areas and 8% even in urban areas. In India, in 1973, when an active search for hidden foci was first carried out, it was revealed that less than 5% of all cases were reported in the entire country.

As the smallpox eradication campaign progressed, however, the efficacy of smallpox surveillance was considerably increased. National eradication programmes developed search operations for hidden foci even in the most remote areas, particularly when smallpox incidence in these countries became very low. However, there were a few exceptions. In Botswana an outbreak was detected six months after the last case was thought to have been found, and an outbreak in Indonesia followed a gap of 8 months in which no case was reported. Hence it was decided by the WHO Expert Committee for Smallpox Eradication in 1972 that active surveillance should be continued for at least 2 years after the last known case before eradication could be declared. The kind of major surveillance measures undertaken during this 2-year period in each of the countries concerned are illustrated by the following examples.

In India and Bangladesh, massive house-to-house searches were undertaken in the 2 years following the detection of the last

cases. On combining the data for the two countries it is found that an average of 98.2% of the 726,811 existing towns and villages were visited during each of the searches. Three such searches were conducted in India and eight in Bangladesh. No cases were found. Pockmark surveys were carried out in 28 countries of West, Central and southern Africa from 1975 to 1978. Of the total estimated population over 4% (9,059,119) were seen. No pockmarked person was found among children born after the year of the last known case in each country. In Ethiopia and Somalia, where the last endemic foci were detected during 1976 and 1977, the latest assessment results illustrate the intensity of the search for hidden foci; over 75% of the inhabitants had met search workers who enquired about smallpox rumours, over 75% knew about the reward which was offered to them if they found a smallpox case (Fig. 3), and over 70% knew where to report such a case.

The adequacy of all these activities has been verified independently during visits by an international group of experts (the International Commission for the Certification of Smallpox Eradication) convened by the WHO for certification purposes. Seventy-nine countries have been identified as either recently endemic for smallpox or exposed to the risk that an imported case of smallpox might establish endemicity. Of these, 64 countries have already been certified as free of smallpox and the remaining 15 countries are preparing for certification by the end of 1979 (Fig. 4).

### Laboratory investigation of collected specimens

From 1973 to 1978, 11,249 specimens were collected from 51 countries—all situated in the tropical zone of Africa and Asia. All the specimens were tested by the WHO Collaborating Centres in Atlanta and Moscow with at least three standard methods—electron microscopic examination, virus isolation on chorioallantois of embryonated eggs and precipitation in gel testing. As the incidence of smallpox fell, so the hunt for residual foci intensified so that in 1977 and 1978, 8,507 specimens were tested.

Over 650 strains of variola viruses have been isolated, all of

**Fig. 2** Variola virus particles (variola minor) from a specimen taken from the last reported case, 26 October 1977.

which conformed with our previous understanding of the characteristics of this virus. Also, vaccinia virus (smallpox vaccine virus) has been isolated on several occasions, indicating that either the suspect patient had generalised vaccinia, or the specimens were contaminated with vaccinia virus. Monkeypox has been found in 36 sporadic cases of zoonosis in West and Central Africa (see below). And on one occasion, a poxvirus termed 'Lenny virus' was isolated from a person with rash and fever who died in eastern Nigeria in 1969<sup>3</sup>. This virus showed a mixture of the characteristics of variola and vaccinia virus, indicating a possible hybridisation of variola and vaccinia viruses during double infection in man. There was no evidence that this virus was transmitted among the inhabitants in the area.

### Mild and severe smallpox

Laboratory examination of variola viruses isolated during the eradication campaign has shed light on the presence of different subspecies of variola virus. Since the report of the presence of mild smallpox 'Amaas' in southern Africa early this century, it has been recognised that there are two strains of variola virus, one, variola minor, causing fatality rates of less than 1% and the other, variola major, causing fatality rates of 20 to 40% among unvaccinated patients. The epidemiological investigation of 36,069 cases, including 2,444 deaths, during the past two decades indicated that fatality rates vary considerably according to the geographical areas; 15–36% on the Asian subcontinent, 8–13% in Africa and Indonesia, and less than 1% in South America<sup>4</sup>. Laboratory studies of more than 200 isolates obtained from these regions indicated that there were at least three sub-groups (A, B and C) in terms of haemadsorption tests on human embryo cell cultures infected by such isolates at 40 °C (ref. 5). Group A was dominant on the Asian sub-continent where the case fatality rate was highest, group B on the African continent where the case fatality rate was moderate, and group C in South America where it was the lowest. Thus, the conventional classification into variola major and minor appears to be inadequate; instead there might be a spectrum of variola virus strains varying considerably in their pathogenicity to man. Although this might indicate that the selection of a less pathogenic variola virus had occurred during long-established endemicity, it was essential for the global smallpox eradication

programme to exterminate all variola virus, regardless of its pathogenicity to man.

### The possibility of variola virus in animals

In the literature from 1767 to 1949 there are seven references to a smallpox-like disease in non-human primates<sup>6</sup>. Except for the one in Indonesia, which occurred in the Jakarta Zoo in 1949, there was no valid evidence that any of these was true smallpox. Between 1966 and 1970, 7,497 blood and tissue specimens collected from mammals in West Africa were examined for various viruses<sup>7</sup>. Of the specimens, 104 were from non-human primates and 5,517 were from rodents. Among 83 virus isolates obtained there was only a single pox virus (gerbilpox) and it was distinguishable from variola virus. From 1970 to 1975, 1,024 sera were collected from non-human primates from tropical Asia without obtaining any evidence of poxvirus infection<sup>8</sup>.

More important are the epidemiological findings. Notably, in the Philippines and Central America, where smallpox has been eradicated for several decades, it has never returned spontaneously, although in these areas non-human primates are plentiful. Also, during the last 10 years of the smallpox eradication campaign, comprehensive epidemiological investigations were conducted on more than 50,000 outbreaks in South America, Africa and tropical Asia. None of the sources of infection could be traced back to an animal origin.

### Orthopoxviruses in animals

Variola virus is a member of the genus *Orthopoxvirus*. Six important viruses in this group are presented in Table 1. All these viruses have close antigenic relationships. Vaccinia, cowpox and camelpox viruses lack continuous transmissibility in man, but the situation with monkeypox virus and whitepox virus deserves further comment.

**Monkeypox virus:** In 1958 a poxvirus was isolated from an outbreak of pox disease in a captive monkey colony in a laboratory in Copenhagen<sup>9</sup>. The virus was called monkeypox virus. The WHO, in surveys on 27 laboratories from 11 countries conducted in 1968 and 51 laboratories from 25 countries in 1970, came up with 10 previous monkeypox outbreaks in laboratories. In one instance monkeypox virus was isolated from a giant ant-eater which temporarily shared a cage with an infected monkey. No monkeypox infection has been reported in laboratories since 1969. No human infections have been associated with any of these outbreaks but the vaccination status of those in contact with the monkeys is not known.

**Fig. 3** "The World Health Organization offers \$1,000 to the first person reporting an active smallpox case resulting from human-to-human transmission and confirmed by laboratory tests. Valid until global eradication is certified."

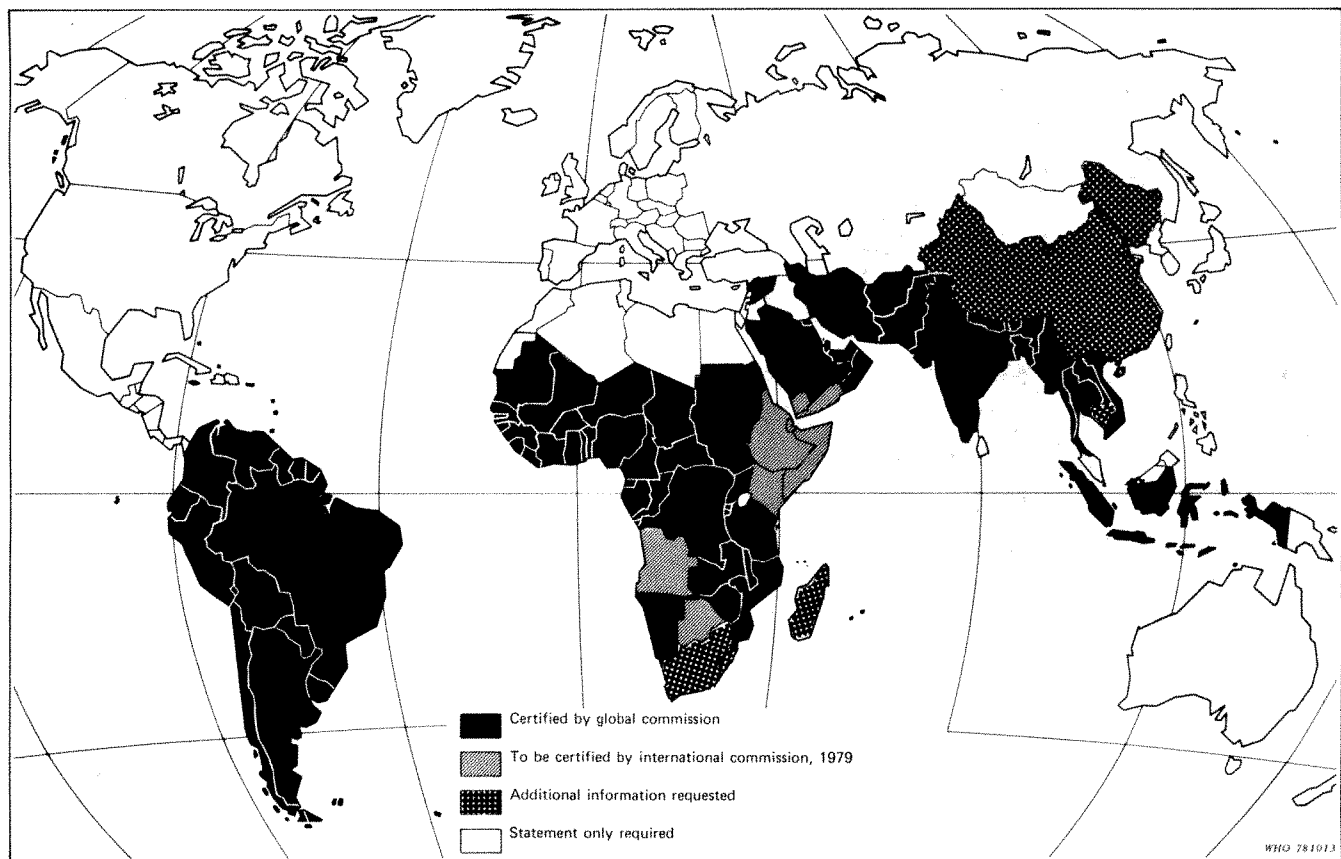

Fig. 4 Global certification of smallpox eradication by the end of 1979.

Monkeypox has not been reported in wild monkeys. The virus was considered a laboratory curiosity until 1970 when the first case of human disease was discovered in remote tropical rain forest of Equateur Region, Zaire<sup>10,11</sup>. From 1970 to 1978, 36 cases of human monkeypox were reported from West and Central Africa. In Zaire, 27 cases have occurred, in Liberia, four, in Nigeria, three, and in the Ivory Coast and Sierra Leone, one each. All the cases have clinically resembled smallpox. Six persons have died, a mortality rate (16%) similar to smallpox in West and Central Africa. Only four patients had a vaccination scar. Most cases occurred in the zone of tropical rain forests where people are hunters and have frequent close contact with a variety of domestic and wild animals (Fig. 5).

There has been no evidence of person-to-person transmission except in two families where second cases occurred 8 and 12 days after the first. These cases suggest secondary transmission unless separate exposures to a common source of infection occurred. Assuming secondary transmission did occur, the potential for interhuman spread of monkeypox can be estimated from the number of susceptible family and community members (those without a smallpox vaccination scar) who had close contact with patients having active disease. Of 56 susceptible contacts, only two (3.6%) came down with the disease. This secondary attack rate is 10 times lower than the transmission rate of 35% for smallpox estimated in West Africa. Tertiary spread of human monkeypox has never been reported.

Special vaccination scar and facial pockmark surveys were carried out in 1975 in populations living near where human monkeypox cases had occurred 4 to 5 years previously in the Ivory Coast, Liberia, Nigeria and Sierra Leone. A relatively low immunity level was found in younger age groups. There were no vaccination scars in 57% of 2,125 children aged 0–4 yr and 29% of 8,047 school-age children, indicating their probable susceptibility to monkeypox infection. No evidence of monkeypox (or smallpox) was found.

The source of human monkeypox infections is as yet unknown. Recent serological studies conducted in the immediate areas where human monkeypox cases occurred have shown a 23% (50/125) prevalence of poxvirus-neutralising antibodies in non-human primates<sup>12</sup>. Of these, three sera showed monkeypox-specific antibody<sup>13</sup>. No human monkeypox has been reported from South America or Asia. Little is known about its natural history, possible animal reservoir or pattern of transmission. Thus, although monkeypox does not appear to frustrate the achievement of smallpox eradication, further research on monkeypox in West and Central Africa with special emphasis on Zaire is warranted. It will be supported by the WHO, for whom the clinical resemblance of the disease to smallpox is one of the problems encountered in its continuing surveillance for smallpox.

**Whitepox virus:** Although attempts to isolate monkeypox virus from animals captured near human monkeypox cases have failed, four whitepox virus isolates have been obtained during laboratory examination from 1970 to 1978. These wild whitepox strains came from the kidney tissue of one chimpanzee, one wild monkey and two rodents all captured in Equateur Region of Zaire<sup>8</sup>. Before this, two strains of whitepox virus had been isolated from routine monkey kidney cell cultures in 1964–65 in another laboratory. The monkeys had come from Malaysia. So far laboratory tests have been unable to determine the nature of these isolates or to distinguish them from variola virus. Note, however, that there has been no evidence of human infection by the virus in the areas where animals for specimen collection were captured.

In 1978, a laboratory reported that cloned variants of some monkeypox virus strains showed the characteristics of whitepox virus and that in hamsters inoculated with a monkeypox virus strain, monkeypox virus was isolated at an early stage of infection but a few whitepox virus isolates were made at a late stage of infection<sup>14,15</sup>. However, the experiences of several other

**Table 1** Comparison of some orthopoxviruses

Characteristics	Variola	Whitepox	Monkeypox	Vaccinia	Cowpox	Camelpox
Isolated from	Man	Ape, monkey rodent	Man, monkey anteater	For vaccine production, origin unknown	Man, cow, large felines	Camel
Pocks on chorioallantois of chick embryo	Small, white	Small, white	Small, pink	Large, white to grey	Haemorrhagic	Small, white

Thymidine kinase sensitivity	+	+	—	—	—	—

investigators have produced conflicting results, namely that white pock variants of monkeypox have not been similar to whitepox virus. Further experiments to clarify these two sets of different observations are now under way in two WHO Collaborating Centres.

Although laboratory studies on whitepox virus have proved somewhat confusing, epidemiological evidence certainly suggests that whitepox virus must differ from variola virus in some way because: (1) no human infections with a variola-like virus have occurred in Malaysia during the last 12 years or in Zaire during the 7-year period since the last smallpox cases were recorded; and (2) it can be presumed that the surveillance system, particularly in Zaire, is sensitive enough to have detected any infection with a variola-like virus as shown by the capability to detect human monkeypox. Nevertheless, this virus merits continued laboratory and field investigations.

### Mutation of poxviruses to variola virus

History suggests that smallpox arose in one area and spread across the world from the initial focus. Although other orthopoxviruses appear to be widespread in nature, there is no evidence of any other 'spontaneous' appearance of smallpox. This is strong evidence against the hypothesis that other poxviruses might give rise to variola virus by mutation.

### Persistence of virus in convalescence and on fomites

Variola virus can be recovered from the urine or nasopharynx of infected patients for not more than 25 days after the onset of the rash<sup>16</sup>. This finding is consistent with epidemiological experience that recovered patients are no longer infectious.

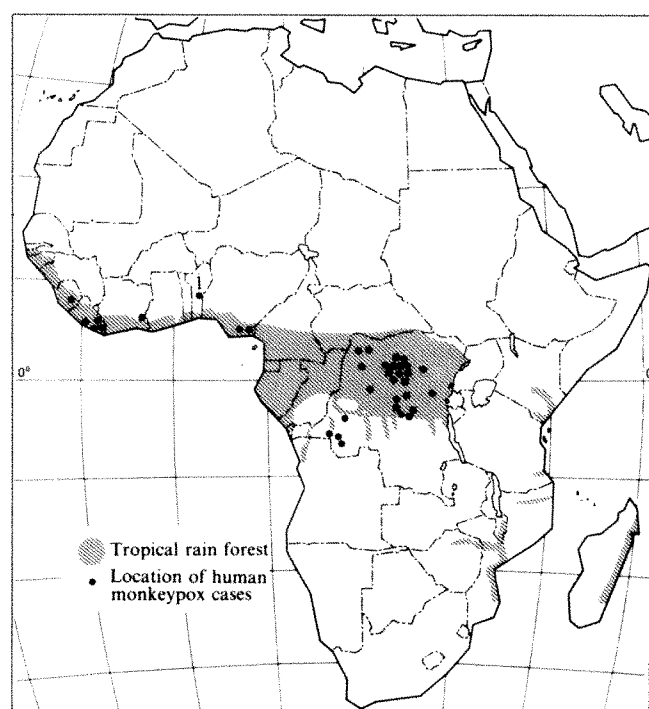

The possibility of smallpox scabs remaining in the houses of patients in previously endemic areas has caused concern, as in 1968 it was reported that scabs kept at room temperature on a shelf in a laboratory in a temperate zone for over 13 years contained viable virus<sup>17</sup>. More recent experiments, however, measuring virus decay in tropical conditions, indicate that virus concentration in scabs may decrease to a non-infective level within three weeks<sup>18</sup>.

The practice of variolation persisted until very recently in some remote tropical areas of Africa and Asia. The last known use of variolation was in Ethiopia in 1976. Samples of variolator's stocks have been collected from Afghanistan, Ethiopia and Pakistan during the past 10 years. Of 21 specimens, 17 did not grow variola virus despite the fact that several specimens showed numerous poxvirus particles on electron microscopy.

Four specimens, all from Afghanistan were positive for viable virus when tested 4–9 months after the variolators had collected their material, but Afghanistan has maintained freedom from smallpox for 5 years; the last case was recorded in 1973. In Ethiopia, once smallpox outbreaks stopped, the practice of variolation also ceased.

### Conclusions

Current evidence from field and laboratory investigations indicates convincingly that when the interruption of smallpox transmission in the human population has been confirmed throughout the world, the risk of re-introduction of the disease will be negligible. This assessment may logically lead to the universal termination of routine smallpox vaccination programmes. This, however, should be accompanied by continuing studies and vigilance. The surveillance of orthopoxvirus

**Fig. 5** Location of human monkeypox cases 1970–78. (1, Patient reported to a hospital in Benin, but developed pockmarks in western Nigeria.)

infections in animals and man as well as laboratory studies of orthopoxviruses should continue and all necessary steps should be taken to minimise the potential danger of live variola virus stocks. To this end, the first meeting of the Global Commission for the Certification of Smallpox Eradication was convened by the WHO in December 1978 and it made comprehensive recommendations in relation to surveillance and research after certification of smallpox eradication, which is expected to take place by the end of 1979.

I thank Professor Keith Dumbell, Dr D. A. Henderson and John Wickett who gave advice, and all colleagues in many countries who provided substantial data for the assessment of the smallpox eradication programme.

*Note added in proof:* Since submission of this article smallpox eradication has been certified in six more countries: Angola, Botswana, Iraq, Lesotho, South Africa and Swaziland. Thus there remain only nine countries which are preparing for certification before the end of 1979.

### Sm–Nd dating of Onverwacht Group Volcanics, southern Africa

P. J. Hamilton, N. M. Evensen & R. K. O’Nions

Lamont-Doherty Geological Observatory of Columbia University, Palisades, New York 10964

H. S. Smith & A. J. Erlank

Department of Geochemistry, University of Capetown, Rondebosch, Cape 7700 South Africa

*Sm and Nd were unaffected by alteration of the Onverwacht lavas permitting for the first time a precise Sm–Nd date ( $3,540 \pm 30$  Myr) to be obtained for this major igneous event.*

THE Onverwacht Group Volcanics, occurring in Swaziland and the Transvaal of South Africa, are probably the most extensively studied Archaean greenstone belt volcanics<sup>1–7</sup>. Ultramafic volcanic rocks were first well documented from the Onverwacht<sup>1–3</sup> and have been generally termed komatiites<sup>4</sup>. Much of the vigorous debate concerning the nature of the Earth’s first stable crust has centred on comparisons of structural, metamorphic and geochemical features of the Onverwacht Group and the Ancient Gneiss Complex<sup>1,5–7</sup>, the oldest element of the granitic terrain surrounding the Swaziland Supergroup.

The Onverwacht Group forms the basal part of the Barberton greenstone belt and together with the overlying sedimentary Fig Tree and Moodies Groups constitutes the Swaziland Supergroup. The Onverwacht Group itself consists of two distinct volcanic units<sup>1</sup>. One of these, the lower ultramafic unit (LUU), is separated from the other, the mafic-to-felsic unit (MFU) by a persistent sedimentary band termed the Middle Marker Horizon. Each unit is subdivided into three formations which from base to top are the Sandspruit, Theespruit and Komati and the Hoogenoeg, Kromberg and Swartkoppie Formations<sup>1</sup>. The

LUU consists mainly of peridotitic and basaltic komatiites with subordinate basic and acid tuffs, and small, generally concordant, penecontemporaneous, felsic porphyry intrusions<sup>2</sup>. The MFU is of less mafic character and has a greater abundance of chemical sediments<sup>3</sup>.

Despite the considerable geological importance of the Onverwacht Group, geochronological studies have been unsuccessful in either precisely defining the time of the volcanism or establishing the temporal relationship between the Swaziland Supergroup and the Ancient Gneiss Complex. Whole rock Rb–Sr studies<sup>8</sup> of the latter indicate repetitive metamorphism and Sr isotope rehomogenisation for ~200 Myr after initial formation of the gneisses ~3,300 Myr ago ( $^{87}\text{Rb}/^{87}\text{Sr} = 1.42 \times 10^{-11} \text{ yr}^{-1}$ ). The initial  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio of  $0.7006 \pm 24$  (all quoted errors are at the 95% confidence level ( $2\sigma_m$ )) for those gneisses at 3,300 Myr when compared with probable mantle values during the Archaean constrain a single-stage crustal prehistory of their parent materials to a period of no more than 100–150 Myr.

Greenschist facies metamorphism which pervades the Swaziland Supergroup<sup>1,9</sup> has perturbed the Rb–Sr systematics such that they now give conflicting impressions as to the age of volcanism. For example, whole-rock Rb–Sr data<sup>10</sup> from the felsic volcanics suggest an age of  $2,570 \pm 40$  Myr, whereas Rb–Sr results for whole rock mafic volcanics provide no useful geochronological information<sup>10,11</sup>. The Rb–Sr ages obtained on sediments of the Swaziland Supergroup are  $3,280 \pm 70$  Myr for

Fig. 1 C1-chondrite normalised<sup>23</sup> abundance patterns for two pillow margin(a)–interior(b) pairs.

the Middle Marker Horizon<sup>12</sup> and  $2,920 \pm 20$  Myr for the Fig Tree Group<sup>13</sup>. These results provide minimum times for the deposition of the sediments and indicate that the Rb–Sr data for the felsic volcanics reflect metamorphic resetting at 2,570 Myr (ref. 10). The U–Pb<sup>14</sup> results obtained on zircon and sulphide separates from felsic volcanics of the MFU yield a slightly older age than the Rb–Sr data at  $\sim 3,310$  Myr. Furthermore, an internal isochron obtained from mineral density separates of a basaltic komatiite from the Komati Formation yields a Rb–Sr age of  $3,430 \pm 200$  Myr and a well defined initial  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio of  $0.70048 \pm 5$  (ref. 11).

Despite considerable effort, adequate geochronological data have not yet been obtained on the Onverwacht volcanics. We present here the first definitive age for the Onverwacht volcanism obtained from Sm–Nd analyses of whole-rock samples.

## REE abundances

The difficulty of obtaining reliable ages from the Onverwacht volcanics using a parent–daughter system which involves an alkali and an alkaline earth element is not surprising in view of the evidence for element mobility obtained from volcanic rocks which have suffered low-grade alteration<sup>15–22</sup>. Both Condie *et al.*<sup>22</sup> and H.S.S. and A.J.E.<sup>20</sup> have investigated the effects of metamorphism on the chemistry of Onverwacht volcanics. Whereas H.S.S. and A.J.E.<sup>20</sup> have made detailed investigations of pillow lava margins and interiors, Condie *et al.*<sup>22</sup> have studied the variations within individual massive flows. Both studies, however, indicate variable fractionation of Rb/Sr during alteration and also demonstrate labile behaviour for K, Na, Ba, S, Cu and Zn, for example. Condie *et al.*<sup>22</sup> have further suggested that the light rare-earth elements (REE) have migrated relative to the heavy REE, although the evidence for such a conclusion is sparse.

Table 1 REE abundances for two LUU pillow lavas

	SC-8		SC-11	
	Margin (a)	Interior (b)	Margin (a)	Interior (b)
Ce	10.3	11.5	11.5	11.6
Nd	7.3	7.6	8.0	7.6
Sm	2.21	2.27	2.34	2.27
Eu	0.72	0.76	0.76	0.78
Gd	2.74	2.60	2.90	2.83
Dy	3.13	3.21	3.34	3.16
Er	2.02	2.02	2.17	2.05
Yb	1.88	1.99	2.01	1.89

To further assess the possibility of differential behaviour of REE during the alteration of Onverwacht samples, REE abundances have been determined using precise isotope dilution techniques<sup>23</sup> for two pillow margin–interior pairs previously studied by H.S.S. and A.J.E.<sup>20</sup>. These REE data are presented in Table 1 and plotted relative to average C1 chondrite abundances<sup>23</sup> in Fig. 1. The small differences that exist within each pillow can be readily attributable to differences in phenocryst content and provide little evidence, in this particular instance at least, for differential movement of REE during low-grade alteration. Note that these particular pillow lavas show variations in Rb/Sr between margin and interior of between 20% and 400%<sup>21</sup>. The successful application<sup>24–27</sup> of the Sm–Nd system to the dating of Archaean igneous rocks of diverse metamorphic grade in general militate against metamorphic disturbance of Sm–Nd systematics.

## Sm/Nd ratios

The samples used in this study are from the type areas of the Theespruit (LUU), Komati (LUU) and Hoogenoeg (MFU) Formations, and were selected for optimum spread in Sm/Nd ratio coupled with preservation of original textures and relict

Fig. 2 Sm–Nd evolution diagram for the samples from the lower ultramafic unit. The data yield an age of  $3,540 \pm 30$  Myr and an initial  $^{143}\text{Nd}/^{144}\text{Nd}$  ratio of  $0.50809 \pm 4$  with errors quoted at the  $2\sigma_m$  level.

mineral content. None of the samples is totally fresh and typically, olivine is serpentinised, plagioclase sericitised and glass devitrified. Other common secondary minerals include calcite, tremolite, epidote, chlorite and talc. Sm and Nd concentrations and  $^{143}\text{Nd}/^{144}\text{Nd}$  ratios were determined (see refs 24 and 32 for analytical details) for 10 samples from the LUU and two from the MFU (Table 2). Sm–Nd data for samples from the LUU, which range from acid pyroclastics to spinifex-textured ultramafics, are plotted on a Sm–Nd evolution diagram in Fig. 2. The best-fit regression line<sup>28</sup> through the data points corresponds to an age of  $3,540 \pm 30$  Myr and an initial  $^{143}\text{Nd}/^{144}\text{Nd}$  ratio of  $0.50809 \pm 4$ . ( $^{147}\text{Sm}\lambda = 6.54 \times 10^{-12} \text{ yr}^{-1}$ ). The data for the seven mafic and ultramafic samples alone yield an age of  $3,510 \pm 60$  Myr and an initial  $^{143}\text{Nd}/^{144}\text{Nd}$  ratio of  $0.50813 \pm 7$  which are not significantly different from those obtained from all the LUU data.

\*  $^{147}\text{Sm}/^{144}\text{Nd}$  ratios are determined to a precision of 0.2% at the  $2\sigma_m$  level.

Inclusion of the data for the two samples from the MFU, though not plotted in Fig. 2, results in a less precise but indistinguishable age of  $3,570 \pm 50$  Myr and an initial  $^{143}\text{Nd}/^{144}\text{Nd}$  of  $0.50807 \pm 6$ . The Sm–Nd data satisfy the normal criteria for designating the regression line an isochron. These results do not resolve the time interval, represented by the Middle Marker Horizon, between the volcanic activity of the LUU and the MFU<sup>1</sup>.

If a single-stage mantle source history is assumed for the LUU volcanics from 4,550 Myr until 3,540 Myr ago and the  $^{143}\text{Nd}/^{144}\text{Nd}$  ratio 4,550 Myr ago was equal to that of the Angra dos Reis achondrite ( $0.50682$ )<sup>29</sup> then the time-integrated Sm/Nd ratio for this interval was  $0.297 \pm 0.005$ . This value is within error of those estimated from whole-rock isochron studies of the Isua<sup>25</sup>, Rhodesian<sup>24</sup> and Monroe Township<sup>27</sup> greenstone belt volcanics (Table 3) and together support the conclusion of DePaolo and Wasserburg<sup>30,31</sup> that Archaean mantle evolved with approximately chondritic Sm/Nd.

The peridotitic komatiites represent large degrees of partial melting whose primary abundance ratios of large ion lithophile elements may closely approximate those of their source region. Four samples of this rock type analysed in this study have Sm/Nd ratios which range from 0.270 to 0.302 and are within about 10% of the time-integrated Sm/Nd ratio of their source.

## Conclusions

Reliable initial  $^{87}\text{Sr}/^{86}\text{Sr}$  data for the Onverwacht volcanics could not be obtained from any of the samples available<sup>21</sup>. However, if the precise initial  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio determined by Jahn and Shih<sup>11</sup> for a LUU basaltic komatiite is assumed to be that characterising the LUU source region 3,540 Myr ago then an estimate of the time-integrated Rb/Sr ratio of the source can be obtained in a manner analogous to that used for the Sm/Nd ratio. The calculated time-integrated Rb/Sr ratio is  $0.034 \pm$

0.001, which is similar to that of 0.03 suggested previously<sup>31,32</sup> on the basis of the correlation of Nd and Sr isotope compositions in oceanic basalts.

Resolution of the temporal relationships between the Onverwacht Group and the Ancient Gneiss Complex must await further geochronological data for the latter which are of comparable precision to those reported here for the Onverwacht. Although the Onverwacht volcanics are of similar age to the Amitsoq gneisses<sup>33–35</sup> of West Greenland they do not represent the oldest known basic crust. The Isua metavolcanics which have been precisely dated by both U–Pb (ref. 35) and Sm–Nd methods<sup>25</sup> are some 200 Myr older.

We thank G. Wesselmann for skilled technical assistance. This work was supported by NSF grant EAR 75–20891.

# Hydrogen production from coal, water and electrons

Robert W. Coughlin & M. Farooque

Department of Chemical Engineering, The University of Connecticut, Storrs, Connecticut 06268

*Coals and other forms of solid carbonaceous fossil fuel are oxidised to oxides of carbon at the anode of an electrochemical cell and hydrogen is produced at the cathode, these gases being produced in relatively pure states. The reaction proceeds at very mild temperatures and at operating electrical potentials significantly lower than the thermodynamic potential of water electrolysis. Although the reaction is readily observable at room temperature, the observed activation energies and the expected decomposition temperatures of the presumed intermediates suggest that much more rapid and steadier oxidation rates might be achieved at higher temperatures in the range 200–600 °C.*

FOSSIL fuels and water are the major raw materials used to manufacture hydrogen although electrical energy produced by nuclear fission may become important for future production of hydrogen by electrolysis. Hydrogen is a key chemical for purifying petroleum of environmentally polluting ingredients; it is also important for converting the solid fossil fuel coal into clean fluid fuels. Mills<sup>1</sup> has specified hydrogen as the most costly ingredient in such conversions, the chemistry and technology of which are reviewed elsewhere<sup>1,2</sup>.

We report here a newly developed electrochemical process which converts coal and water into two separate gaseous products: one comprising essentially gaseous oxides of carbon and the other essentially pure hydrogen. The process chemistry takes place at mild temperatures (even room temperature) and the gaseous products are essentially free of impurities such as ash, tar and sulphur compounds. This new electrochemical gasification process involves the anodic oxidation of coal at an electrode for which we postulate the half-cell reaction of the carbon in coal:

in combination with a corresponding half-cell reaction at the cathode:

The net sum of these half-cell reactions (1) and (2) is the equation for the predominant reaction in the electrochemical gasification of coal:

This electrochemical gasification process, instead of producing a complex mixture containing H<sub>2</sub>, CO, CO<sub>2</sub> and impurities (as in conventional steam-carbon gasification), produces relatively pure streams of carbon oxides in the anode compartment and hydrogen at the cathode.

In principle, conventional water electrolysis requires a theoretical thermodynamic electrical energy input [ $\Delta F^\circ = -nFE^\circ$ ] of 56.7 kcal per mol of hydrogen and a corresponding theoretical driving potential of about 1.23 V whereas electrochemical gasification (equations (1)–(3)) requires according to thermodynamic principles only about 9.5 kcal of electrical energy and a reversible potential of only 0.21 V to produce 1 mol of hydrogen. The greatly lowered electrical energy requirement for the latter process results, of course, from the consumption of coal which can be viewed as supplying the additional electrons required by the process.

Of course, the stoichiometric reactions written above mask reaction mechanism(s) which as yet can only be speculative. Perhaps the primary electrode process is the discharge of OH<sup>−</sup> at the anode to produce a radical which attacks the coal. Overall, the carbon of the coal might also be viewed as an oxygen acceptor.

Conventional production of hydrogen from coal uses steam-carbon reactions to produce synthesis gas (CO and H<sub>2</sub>) by a strongly endothermic reaction which must be conducted at temperatures sufficiently high (~800 °C) to assure favourable equilibrium. Synthesis gas must then be purified to remove sulphur compounds and other impurities followed by reaction with water to shift the CO/H<sub>2</sub> ratio as required. Coal gasification technology is discussed in detail elsewhere<sup>2,3–5</sup>.

We have conducted electrochemical gasification of three coals, one lignite and one char (obtained from the Pittsburgh Energy Research Center of the US Department of Energy) by anodic oxidation in the apparatus of Fig. 1. Typical results recorded in Table 1 show substantial oxidation currents at applied potentials significantly lower than those necessary to electrolyse aqueous electrolytes, compared with control experiments made in the absence of coal. Hydrogen was produced at the cathode and carbon dioxide containing 3–7% carbon monoxide at the anode. Oxidation of the coal apparently requires contact with the anode—only background current is measured if the anode is surrounded by a porous membrane which prevents the close approach of the coal particles but permits transport of species dissolved in the anolyte.

In these early experiments, Montana Rosebud char gave higher current and seemed easier to oxidise anodically than the parent coal. Based on other experiments with active carbon, diamond and graphite we attribute this behaviour to the higher surface area, smaller particle size and more graphitic nature of the char as compared with the parent coal. Susceptibility of a carbonaceous particle to anodic oxidation may be related to the electrical conductivity of the particle.

Figure 2 shows the inter-relationship of oxidation current, temperature and coal-to-electrolyte concentration; increasing such concentrations or temperature causes current to increase as

**Fig. 1** Stirred slurry gasification cell. Supporting electrolyte H<sub>2</sub>SO<sub>4</sub>, 475 ml volume. Anode and cathode were Pt gauge 52 mesh with respective areas of 96.5 cm<sup>2</sup> and 158 cm<sup>2</sup>.

**Table 1** Comparison of oxidation rates of different coal samples

Coal	Potential of oxidation (V)	Coal concentration ( $\text{g cm}^{-3}$ )	Oxidation rate (mA)
Montana Rosebud char	0.78	0.475	8.20
North Dakota lignite	0.83	0.475	9.00
Pittsburgh coal	0.875	0.475	5.30
Illinois no. 6	0.875	0.475	3.00
Montana Rosebud coal	0.78	0.475	1.50

Electrolyte, 3.7 M  $\text{H}_2\text{SO}_4$ ; temperature, 23 °C; electrode area, 6.5  $\text{cm}^2$ ; coal slurry concentration, 0.475  $\text{g cm}^{-3}$ ; particle size, 250  $\mu\text{m}$  and below; experimental apparatus as in Fig. 1. Control experiments with no coal, lignite or char produced currents of only about 0.05 mA.

expected. The temperature dependence of oxidation rate leads to an estimate of apparent activation energy of about 10–12  $\text{kcal mol}^{-1}$  for North Dakota lignite at 1 V. Such low activation energy suggests that the rate determining step may not be a typical chemical reaction. Particle size effects have also been observed but they are complex and seem to be time dependent. The ash content, porosity and other properties of the particles may be size dependent and particle size is also related to momentum available for a particle to penetrate the nernstian layer at the anode. We have also obtained comparable results with electrodes other than Pt (such as graphite) and other electrolytes (such as HCl). The higher the potential the greater the oxidation current. As the coal is consumed by oxidation at a given potential the current diminishes as shown in Fig. 3 where current is plotted against the potential for various extents of coal consumption as a parameter. Anodic oxidation of carbon anodes has been investigated previously<sup>6</sup>. The controlled oxidation of purer carbons, whether by electrochemical or chemical means, results in the formation of surface oxides such as hydroxyl, carbonyl or carboxyl groups<sup>6–8</sup>. We believe that such oxides also form during the anodic oxidation of coal and, as they increase in concentration on the surface of the coal particles, the potential required for additional oxidation increases. These surface oxides of carbon decompose to gaseous oxides of carbon on heating and this is consistent with the experimental observation that as temperature increases lower potentials are required to produce the same rate of oxidation. The gradual decrease of the reaction rate may be attributed to a corresponding accumulation of chemisorbed oxygen in the form of surface functional groups on the coal<sup>6–8</sup>. Based on the known decomposition temperatures<sup>9</sup> for such surface compounds it should be possible to maintain a higher and steady oxidation rate at 200–600 °C, perhaps even at applied potentials lower than those reported here. Of course, such higher temperatures would entail operation at pressures above atmospheric.

Some experiments were performed in which, after significant consumption of the coal had taken place by anodic oxidation at about 100 °C, and the anodic current at 1 V had decreased to low values, the coal was removed from the electrolyte and heated to about 200 °C to decompose surface oxides. When this coal was returned to the anolyte, high oxidation currents were measured at 1 V again, and these currents were almost equal to those provided by virgin coal at the same conditions. Reactivity could also be restored by extracting reacted coal with hydrocarbon solvents.

Surface carboxyl groups on coal or smaller carboxylated fragments can probably react through a Kolbe-type pathway to form aliphatic type hydrocarbons:

Surface free radicals,  $\text{R}\cdot$ , might also form by

Such reactions may be responsible for the tar-like substance that can be extracted from anodically oxidised coals using hydrocarbon solvents. For example, acetone extracted about 5% of the weight of 25%-consumed NDL to form a dark, reddish-

**Fig. 2** Effect of coal concentration on the oxidation rate. (North Dakota lignite; particle size, 44  $\mu\text{m}$  and below; supporting electrolyte concentration, 4.13 M  $\text{H}_2\text{SO}_4$ ; oxidation potential, 1.00 V; experimental apparatus as in Fig. 1 except anode area 6.5  $\text{cm}^2$ . ●, 78 °C; ■, 59 °C; ▲, 39 °C.

brown solution, whereas a similar treatment of the parent coal produced an extract that remained almost clear.

### Gases produced and the current efficiency

During oxidation of ND lignite at 114 °C and at potentials near 0.85–1.0 V the gas produced at the cathode was essentially pure  $\text{H}_2$ . Based on 12 experiments in each of which about 100  $\text{cm}^3$  of  $\text{H}_2$  was collected, the mean current efficiency (defined as: mol  $\text{H}_2$  collected/mol  $\text{H}_2$  corresponding to coulombs passed) was 1.00 with a standard deviation of  $\pm 0.022$ . The gas produced within the anode compartment was almost pure  $\text{CO}_2$  with small amounts of CO ranging from about 7% early in the electrolysis (about 1,870 C passed, equivalent to about 0.34% of coal consumed) to a steady-state value of about 3% attained at about 3,740 C passed (equivalent to about 0.68% of coal consumed). The volume ratio of the gases collected at the cathode to those at the anode ranged from  $\sim 3.5$  to  $\sim 8$ ; the higher ratios were obtained at the beginning of the experiment but then decreased. According to reaction (3) the gas ratio should be about 2. In the present conditions, however, a significant portion of the carbon oxides presumably remained bound to the coal (probably as  $-\text{COOH}$ ,  $-\text{CHO}$  and  $-\text{CH}_2\text{OH}$  groups) and this would account for the gas volume ratios  $> 2$ . The decrease in these ratios as an experiment progresses may be attributed to the build-up of oxygen on the carbon surface until a steady-state saturation is reached. Higher temperatures should cause more oxides of carbon to be liberated from the coal with an attendant lowering of the ratio of cathode-to-anode gas production rate. Some electrolyte-soluble, (probably oxygenated) organic compounds

**Fig. 3** Effect of potential on the oxidation rate as the reaction proceeds. (North Dakota lignite; coal slurry conc., 0.069  $\text{g cm}^{-3}$ ; supporting electrolyte, 5.60 M  $\text{H}_2\text{SO}_4$ ; particle size, 125–149  $\mu\text{m}$ ; temperature, 114 °C experimental apparatus, as in Fig. 1 with anode area 96.5  $\text{cm}^2$ . Total carbon consumed: ○, 0.156%; ●, 6.35%; □, 21.1%; ■, 29.2%.

were also produced as indicated by total organic carbon assays of the filtered electrolyte after extended anodic oxidation of coal.

A qualitative but sensitive mass spectrometric analysis was made of the gases produced at both anode and cathode. Note that no lines were observed for molecular weights corresponding to  $\text{SO}_2$  or  $\text{H}_2\text{S}$ , even though the parent lignite contains significant sulphur.

We can compare the efficiency of our process (coal-consuming water electrolysis) with ordinary water electrolysis. In water electrolysis the energy required to split the water molecule is supplied solely by electricity, whereas in our new process the required energy is supplied only in part by electricity with the balance arising by way of the concomitant anodic oxidation of coal. The following quantitative development gives a first order approximation of how much energy comes from each such source and thereby provides a rough feeling for efficiency. The energy consumed by conventional water electrolysis conducted at a potential of  $E_2$  to produce  $N_{\text{H}_2}$  moles of  $\text{H}_2$  is  $2N_{\text{H}_2}FE_2$  whereas the energy required by the present process operating at a potential of  $E$  is:

$$E \int_0^t i \, dt + N_{\text{C}}(-\Delta H)$$

where  $E$  is the potential applied across the cell;  $i$  is the current; and  $t$  is time  $N_{\text{C}}$  is the number of mol of carbon consumed and  $\Delta H$  is the enthalpy of combustion of carbon to  $\text{CO}_2$ .

The foregoing expression can be simplified by assuming a constant operating potential  $E$ , and noting that:

$$N_{\text{H}_2} = \int_0^t i \, dt / 2F \quad \text{and} \quad N_{\text{C}} = 1/2 N_{\text{H}_2}$$

where  $F$ , the Faraday constant, is  $96,500 \text{ C equiv.}^{-1}$ .

Eliminating  $\int_0^t i \, dt$  and  $N_{\text{C}}$  the expression for total energy consumption by our process becomes

$$2FN_{\text{H}_2}E + 1/2N_{\text{H}_2}(-\Delta H)$$

Received 18 December 1978; accepted 21 March 1979.

2. Kirk, E. R. & Othmer, D. F. *Encyclopedia of Chemical Technology*, Vol. 4 (Interscience, New York, 1966).
3. Squires, A. M. *Science* **184**, 340-46 (1974).

The relative energy usage (REU) is accordingly:

$$\begin{aligned} \text{REU} &= \left( \frac{\text{ordinary electrolysis}}{\text{coal-assisted electrolysis}} \right) \\ &= \frac{2N_{\text{H}_2}FE_2}{2FN_{\text{H}_2}E + 1/2N_{\text{H}_2}|\Delta H|} \\ &= E_2/(E + |\Delta H|/4F) \end{aligned}$$

Inserting  $|\Delta H| = 94,100 \times 4.18 \text{ J mol}^{-1}$  and the value of  $F$  gives:

$$\text{REU} = E_2/(E + 1.02)$$

Practical values of  $E_2$  for conventional electrolysis are about 2 V whereas values of  $E$  observed in the present work have ranged from  $\sim 0.8$  to  $\sim 1.0$  V at room temperature. This means that the total energy consumption is about the same ( $\text{REU} \approx 1$ ), per unit of hydrogen produced, for ordinary water electrolysis and for coal-assisted water electrolysis conducted in the experiments near room temperature reported here. In the case of electrochemical gasification to hydrogen, however, about half the required energy comes directly from coal and half from electricity. We expect that the total energy requirement for coal-assisted water electrolysis can be lowered further by carrying it out at higher temperatures thereby permitting operation at lower potentials ( $E$ ) than 0.8–1.0 V. Note that we have treated coal as pure carbon and assumed it is completely oxidised to  $\text{CO}_2$  at the anode in the above approximate assessment of REU. Such simplification ignores the complications arising from the variable hydrogen and oxygen content of different coals and the question of the different relative proportions of  $\text{CO}$ ,  $\text{CO}_2$  and small amounts of non-gaseous carbon oxides that may be formed at different operating conditions.

The results presented here represent a new technical concept for preparation of hydrogen from the electrochemical reaction of water and coal. Additional results will be reported elsewhere.

We thank the University of Connecticut and the US Department of Energy for financial support. Larry Veneziano provided experimental assistance.

## The origin of baryons in the Universe

THERE are several clues to the history of the early Universe. The 3-K microwave background indicates that the Universe was highly isotropic when it was about a half million years old, and the abundance of  $^4\text{He}$  (also  $\text{D}$ ,  $^3\text{He}$  and  $^7\text{Li}$ ) indicates that nucleosynthesis was taking place when the Universe was about three minutes old. These two facts are strong evidence that the Universe began from a hot big bang<sup>1</sup>. In addition, Hawking, Ellis and Penrose have proved (within general relativity) that the existence of the 3-K radiation implies the Universe must have been singular in its past<sup>2,3</sup>. The existence and clustering of galaxies indicate there were some deviations from homogeneity in the early Universe. Perhaps the most curious fact about the

Universe is that it is composed almost entirely of matter (the Universe contains negligible amounts of antimatter) and that the number of baryons per photon ( $\sim$  baryon/entropy ratio) is between  $10^{-10}$  and  $10^{-8}$  (ref. 4). If baryon number is absolutely conserved, then it follows that the baryon number of the Universe must be viewed merely as an initial condition. Recent ideas in particle physics when applied to the early Universe may explain how an initially baryon-symmetrical (zero net baryon number) Universe could have evolved into one with net baryon number. Here, we will discuss these ideas and other interesting astrophysical implications.

The striking success of the Weinberg-Salam  $\text{SU}(2) \times \text{U}(1)$  gauge theory of the weak and electromagnetic interactions<sup>5</sup> and of the  $\text{SU}(3)$  colour gauge theory of the strong interactions<sup>6,7</sup> has

motivated grand unified gauge theories of the strong, weak and electromagnetic interactions<sup>8-12</sup>. A common feature of all these grand unified theories is baryon non-conservation mediated by a very heavy (Higgs and/or gauge) boson(s) of mass  $\sim 10^{10}$ – $10^{16}$  GeV  $c^{-2}$ . In addition, these theories naturally violate CP (particle-anti-particle symmetry).

At present energies (even those of the largest proposed particle accelerators), these baryon non-conserving processes are not important; however, in the early Universe, when  $kT \geq m_x c^2$  ( $m_x$  is the mass of the boson which mediates baryon non-conserving reactions) these processes would have been roughly the same strength as the other interactions and an initially baryon-symmetrical Universe could have evolved into one with net baryon number. Several authors<sup>13-16</sup> have pointed out that in addition to CP and B violations one must also have departures from thermal equilibrium to produce baryon asymmetry. Departures from equilibrium occur naturally in the early Universe when reaction rates cannot keep pace with the expansion rate of the Universe. Several schemes have been proposed<sup>13,14,16-19</sup> which produce a baryon/photon ratio of  $\sim 10^{-10}$ – $10^{-8}$ . We shall describe the one proposed by Weinberg<sup>16</sup>, and discuss the astrophysical consequences of cosmological baryon production and a new hybrid scheme using an earlier idea of Hawking<sup>20</sup> as well as the new unification theories.

In the Weinberg scheme, the Universe begins as a baryon-symmetrical hot soup containing all the fundamental particles (leptons, quarks, photons, X-bosons). When the lifetime of the X-boson is approximately the age of the Universe,  $kT$  is less than  $m_x c^2$ , so that the X- and  $\bar{X}$ -bosons freely decay (their decay products are not energetic enough to regenerate them). At this temperature baryon non-conserving reactions have become ineffective (reaction rates < expansion rate) so that any baryon number generated will not be destroyed. The decay products of the  $\bar{X}$ -bosons have a mean net baryon number  $B_{\bar{X}} \neq -B_X$ ,  $B_X$  = the mean net baryon number of the decay products of X-bosons (this is permitted by CP and B violations). Therefore, the Universe acquires a baryon/photon ratio proportional to  $(B_X + B_{\bar{X}})$ , which is itself proportional to the size of the CP violation. From this point forward the Universe evolves with the baryon/photon ratio remaining constant or decreasing with the generation of additional entropy or with the decay of baryons.

Because grand unified theories do not conserve B, they also predict that the proton is unstable. In the SU(5) and O(10) unification theories,  $\tau_p \sim \alpha^{-2} m_x^4 / m_p^5 \sim 10^{32 \pm 1}$  yr ( $\alpha$  ~ fine structure constant  $\cong 1/137$ )<sup>21,22</sup>. The current lower limit on the proton lifetime is  $10^{29}$  yr and comes from the Case-Wit-Irvine neutrino experiment in South Africa<sup>23</sup>. Lande *et al.* are using the neutrino telescope at Homestake Mine in Lead, South Dakota (for this experiment neutrinos are the background!) to explore lifetimes of  $\sim 10^{31}$  yr (by mid-1979) and hope to be able to have developed a sensitivity to lifetimes of  $\sim 10^{32}$  yr within 2 yr (K. Lande, personal communication). A positive result from a proton decay experiment would be strong evidence for baryon generation in the early Universe. In addition, if the Universe is open, such a result means that it will eventually be devoid of baryonic material.

In the gravitational instability theory of galaxy formation and clustering, small initial density fluctuations grow with time and eventually become of the order of unity, leading to the formation of galaxies and clusters of galaxies<sup>24</sup>. The initial fluctuations are of two types: adiabatic and isothermal. In an adiabatic fluctuation both the matter and radiation are perturbed and are related by  $(\delta\rho/\rho)_{\text{matter}} = 3(\delta T/T)_{\text{radiation}}$ . In an adiabatic fluctuation the baryon/entropy ratio remains constant. In an isothermal fluctuation the radiation does not participate in the perturbation ( $\delta T/T = 0$ ) and so the baryon/entropy ratio is not constant. The adiabatic perturbations are subject to damping (while the matter and radiation are coupled) and only fluctuations on mass scales  $\geq 10^{12} M_\odot$  will survive and grow to the order of unity. Isothermal perturbations are not subject to damping, and fluctuations on mass scales  $\geq 10^5 M_\odot$  will grow to the order of unity. If the initial fluctuations were adiabatic then the 3-K background should

show variations  $\Delta T/T \sim 10^{-3}$  on angular scales of  $\sim 30$  arc s. Such variations have not been seen and are just below the sensitivity level of current experiments<sup>25</sup>.

If the baryons in the Universe were generated as outlined above, the baryon/entropy ratio would depend only on microphysics (the grand unified theory). Therefore, the initial temperature fluctuations in the Universe would not give rise to baryon/entropy fluctuations (unless the fluctuations were so large that some parts of the Universe were never hotter than  $m_x c^2/k$  and no net baryon number was generated). Any initial density perturbations must be adiabatic rather than isothermal. This fact is related to the problem of galaxy formation and clustering in the Universe.

One way around the elimination of initial isothermal fluctuations is through primordial black holes. Hawking has shown that a black hole of mass  $m$  (in grammes) should emit a spectrum of particles like a black body with a temperature of  $\sim 10^{26}$  K  $m^{-1}$  (ref. 26). As a black hole radiates, it loses mass and ultimately evaporates in a time  $\sim 10^{-26} m^3 N^{-1}$  s ( $N$  ~ number of particle species it can emit)<sup>27</sup>. As it is evaporating its temperature increases; when  $kT \sim m_x c^2$  a black hole can emit X- and  $\bar{X}$ -bosons (in equal numbers). When these bosons decay they will produce a net baryon number  $\sim (B_X + B_{\bar{X}}) \times (\text{number of X, } \bar{X}\text{-pairs emitted})$ . All black holes with an initial mass  $m$  such that the corresponding temperature is  $\leq m_x c^2/k$  ( $m \geq 10^{13} m_x^{-1}$ ,  $m_x$  in GeV) will eventually produce the same number of X,  $\bar{X}$ -pairs and hence the same net baryon number. (This is because no X,  $\bar{X}$ -pairs will be produced until the mass of the black hole has decreased such that its temperature  $\sim m_x c^2/k$ .) The rest of the mass of an evaporating black hole will eventually be converted into photons (entropy), so that the baryon/entropy ratio created by an evaporating black hole is proportional to  $m^{-1}$ . The entropy and baryon number of the Universe could be produced from an appropriate primordial spectrum of black holes (Hawking first suggested baryon and entropy production by primordial black holes, although he did not elaborate on a mechanism<sup>20</sup>). In addition, as the baryon/entropy ratio produced by an evaporating black hole depends on its mass, the distribution and mass spectrum of primordial black holes could lead to both isothermal and adiabatic initial density fluctuations in the Universe. For example, suppose the Universe was initially isothermal and without net baryon number. Let the net baryon number be produced by a non-uniform spatial distribution of primordial black holes of mass  $m$ . If the entropy added by the evaporation of the black holes is small (let  $m$  be  $\sim 10^{13} m_x^{-1}$  g) the density fluctuations caused by the spatial distribution of black holes will be nearly isothermal. For some values of  $m_x$ , baryon production by other routes is negligible because when the X and  $\bar{X}$  decay baryon non-conserving collisions are still effective and any baryon excess produced is neutralised. In these cases primordial black holes can act as 'seeds', evaporating after nm-conserving collisions become ineffective and thereby generating a baryon excess that is not neutralised.

In conclusion, we can say that recent developments in the unification of elementary particle interactions by gauge theories may provide an explanation for what seemed to be an arbitrary initial condition—the baryon/entropy ratio. In addition, if this explanation is correct, it is directly relevant to the question of initial density fluctuations and galaxy formation.

## IUE observations of the symbiotic star CH Cygni during an active phase

THE spectrum of CH Cygni usually has the appearance of a normal M6 III star, but at intervals of several years, it has outbursts during which it shows the characteristics of a symbiotic star, that is a blue continuum extending shortward of the Balmer discontinuity, and emission lines of He I, Fe II, [Fe II], [S II], [O III]; the Balmer lines and the H and K lines of Ca II present emission wings. The observations of CH Cygni reported here were made to determine whether a symbiotic star is a binary system composed of an M6 giant and a hot subdwarf, or whether it is a cool star surrounded by a thick corona.

Outbursts were observed: in September 1963 (ref. 1), the star had already returned to normal by August 1965; in June 1967 (ref. 2) the spectrum was followed by Faraggiana and Hack<sup>3</sup> until December 1970 when the star returned to normal; another

outburst was observed in August 1977 (refs 4, 5), the spectrum was observed by Faraggiana with the coude spectrograph at the 152-cm telescope of the Haute Provence Observatory, and in June and September 1978 still had the characteristics of a symbiotic star. Our observations of the UV spectrum of CH Cygni reported here, made with IUE on April and July 1978 were therefore taken during its active phase.

The most obvious hypothesis for explaining symbiotic stars is that they are binary systems formed of a late-type giant and a hot subdwarf which occasionally has outbursts. Or the cool star may be surrounded by an extended and thick corona heated by shock waves, which is supposed to be responsible for the blue continuum and the emission lines<sup>6,7</sup>. A third hypothesis<sup>8</sup>, that a hot star is surrounded by a cool, optically thick envelope, was discarded by the observations of CH Cygni in 1967-70 (ref. 3) because they gave clear evidence that the blue continuum was filling up the M6 photospheric lines, a distinctive phenomenon which was again observed in the spectra obtained by Faraggiana in June and September 1978 (personal communication).

Several symbiotic stars present orbital motions; however, CH Cygni does not show any evidence of periodic radial velocity variations. Instead, our observations supported the hypothesis that shock waves heat the extended envelope surrounding the M6 giant star. Photometric observations by Slovak and Africano<sup>9</sup>, however, indicate that CH Cygni presents a rapid flickering, characteristic of the cataclysmic variables, most of which are close binary systems. According to Slovak and Africano<sup>9</sup>, the flickering provides the strongest evidence for the interpretation of CH Cygni as a binary system undergoing mass transfer.

To decide which hypothesis could explain the spectrum of CH Cygni, it was observed with IUE, in the low resolution mode and in the short-wave range on 22 April (using the 3" aperture) and on 31 July 1978 (using the large aperture, 10" × 20").

The UV spectrum of CH Cygni is characterised by an almost flat continuum from  $\lambda 1250$  to  $\lambda 1700$  with a mean flux of about  $5 \times 10^{-13} \text{ erg s}^{-1} \text{ cm}^{-2} \text{ \AA}^{-1}$  (determined from the July spectrum, observed with the large aperture), by a very strong emission at  $\lambda 1302$  (the flux at the centre of the emission is about 5 and 4 times the flux in the adjacent continuum, in April and July respectively) due to O I, and by several fainter emissions, which in many cases can be barely distinguished from high points on the continuum; moreover, several absorption lines are present. The energy distribution in the continuum at  $\lambda > 1700$  is strongly

**Fig. 1** The spectra of CH Cygni observed in April and July. The ordinates are  $\log F$ , where  $F$  is the flux at the Earth ( $\text{erg cm}^{-2} \text{ s}^{-1} \text{ \AA}^{-1}$ ) given by the relation  $F_{\lambda} = N_{\lambda} S_{\lambda}^{-1} t^{-1}$ , where  $N_{\lambda}$  is the IUE flux number,  $S_{\lambda}$  the camera sensitivity and  $t$  the exposure time in seconds. The emissions are indicated by arrows.

**Fig. 2** The far UV spectrum of CH Cygni, observed on 31 July 1978, is compared with that of Beta Lyrae (S2/68 observations) and with the Kurucz, Peytremann and Avrett blanketed models.  $\times$ — $\times$ , Beta Lyrae;  $\bullet$ — $\bullet$ , KPA model,  $T_e = 10,000$  K,  $\log g = 4.5$ ;  $\circ$ — $\circ$ ,  $T_e = 11,000$  K,  $\log g = 4.5$ ;  $+$ — $+$ ,  $T_e = 13,000$  K,  $\log g = 4.5$ . The arrows above the CH Cygni spectrum indicate the position of the emission lines.

affected by the presence of the emissions. Their blending produces in this region a peculiar energy distribution, very similar to that previously observed for Beta Lyrae<sup>10</sup> with experiment S2/68 (spectral resolution about 35 Å) aboard the European satellite TD-1.

The two spectra observed in April and July are almost identical, except for a constant difference in the flux, which is four times lower in April, a difference probably due exclusively to the light loss through the 3" aperture<sup>11</sup> (Fig. 1). Moreover, the July spectrum presents a strong emission at Ly $\alpha$ , which is of geocoronal origin, because it fills up the whole height of the slit, as shown by inspection of the photowrite. No appreciable variations are evident, either, in the region  $\lambda\lambda 3500$ – $5000$  Å, at least from a visual inspection of the spectra taken in June and September 1978.

As it is very difficult to trace a reliable continuum through the various absorption and emission features, we have considered an average curve passing through the majority of these features, but below the strongest emissions and above the strongest absorptions (Fig. 2). We then compared this with the spectra of several stars observed with S2/68 (ref. 12), and with several theoretical models<sup>13</sup>. The best fit along the whole region 1380–1900, common to IUE and S2/68 observations, is obtained with Beta Lyrae, whose spectrum is also characterised by the presence of several strong emissions. As Beta Lyrae has been observed in the high resolution mode with IUE, the identification of the emissions in its spectrum has been a useful guide to the identification of the emissions in the spectrum of CH Cygni. Comparison with normal unreddened stars indicates that the best agreement is found with B9–A0 stars, but only in the region  $\lambda < 1750$  Å, because of the distortion due to the emissions. Atmospheric models for  $T_e \approx 10,000$  K or 11,000 K agree with the observed energy distribution in the region  $\lambda\lambda 1275$ – $1750$  Å (Fig. 2). At  $\lambda > 1750$  Å, the continuum is distorted by the blending of several strong emission features, and at  $\lambda < 1,275$  Å the flux decrease is slower than that predicted by the models. This latter behaviour indicates that the Ly $\alpha$  absorption is much fainter in CH Cygni, an effect we attributed to the presence of geocoronal and stellar Ly $\alpha$  emission.

The magnitude difference  $\Delta m$  with the standard star HD168905,  $B2.5$  V,  $V = 5.24$ , observed with IUE with the large aperture (Selvelli, personal communication), ranges from +9.5 at  $\lambda 1170$  to +6.0 at  $\lambda 1900$ . The magnitude difference with Vega (observed with S2/68 (ref. 12) ranges from +10.3 at  $\lambda 1450$  to +9.3 at  $\lambda 1900$ .

The main contributors to the blends are given in Fig. 1. Absorption lines of multi-ionised atoms like  $\lambda 1175$  C III,  $\lambda 1550$  C IV,  $\lambda 1718$  N IV,  $\lambda 1240$  N V, probably  $\lambda 1767$  and  $\lambda 1771$  O III,  $\lambda 1400$  Si IV are present. All the emission lines, on the contrary, are due to transitions to the ground level of neutral or once-ionised atoms (like  $\lambda 1253$  S II, multiplet 1 (ref. 14);  $\lambda 1281$  C II, 5;  $\lambda 1303$  and  $\lambda 1355$  O I, 2;  $\lambda 1335$  C II, 1;  $\lambda 1533$  Si II, 2;  $\lambda 1785$  P I, 1;  $\lambda 1808$  Si II, 1;  $\lambda 1817$  Si II, 1) and to the strongest lines of iron twice-ionised. The emission at  $\lambda 1640$ , attributed to He II, probably receives an important contribution from the Fe II lines of multiplets 8 and 68, which have the second strongest intensities in this spectral region, after those of multiplet 191, which is a possible explanation for the emission at  $\lambda 1785$ , together with P I.

These observations do not enable us to decide between the two hypotheses outlined above. The UV continuum seems to be the continuation of the optical violet continuum observed during outbursts, whose colour temperatures was found to equal  $\sim 10,000$  K (ref. 3). This temperature is not sufficient to explain the presence of the absorption lines of multi-ionised atoms. If we assume that the UV continuum is due to an increase in brightness of the hypothetic companion or that it arises in a hot corona surrounding the cool star and which becomes optically thick during the active phases then we must assume that mechanical energy, liberated during the outburst, is responsible for the high degree of ionisation of the gas. In contrast the emission lines should form in an extended envelope. The presence of this envelope, where hydrogen is mostly ionised, is indicated by the strong emission of O I at  $\lambda 1302$ . In fact Ly $\beta$  and  $\lambda 1025.77$  O I have almost the same high excitation potential: therefore, Ly $\beta$  emission overpopulates the upper level of  $\lambda 1025$  O I; hence by cascade, emissions at  $\lambda 11287$ ,  $\lambda 8446$  and  $\lambda 1302$  are explained<sup>15</sup>.

It would be necessary to observe the UV spectrum of CH Cygni in periods of quiescence to understand better the nature of the companion, if present, and to study the conditions of the envelope far from the effects of the outbursts.

Note that CH Cygni has been observed again with IUE on 11 March 1979 in the low resolution mode. The spectrum is identical with that observed on July 1978, but the flux is increased by a factor 1.6 over the whole spectral range 1,200–1,900 Å.

This research is based on observations by the IUE collected at the Villafranca Satellite Tracking Station of the ESA. I thank all the staff of the Villafranca Station for their assistance in observ-

ing and reducing the data, and especially Dr P. L. Selvelli for the July observations. This work was supported by a CNR-SAS contract.

## Temperature structure of the uranian upper atmosphere

FROM observations of the occultation of the star SAO158687 by Uranus on 10 March 1977<sup>1,2</sup>, we have determined the temperature structure of its upper atmosphere at two locations on the planet. These are the first temperature measurements within the  $10^{-4}$ – $10^{-2}$  mbar range, which lies several scale heights above the region probed by IR measurements. Although this occultation was noted for the unexpected discovery of the uranian rings<sup>3–5</sup> and ring occultations were observed by several groups<sup>6</sup>, an occultation by the planet itself was seen from only two observatories—the Kuiper Airborne Observatory (KAO) and Cape Town. Here we present the first results from the KAO data: the Cape Town results will be discussed elsewhere<sup>7</sup>.

The data we obtained with the 91-cm telescope aboard the KAO consist of continuous records of the starlight intensity, recorded simultaneously at three wavelengths (6,190; 7,280 and 8,520 Å) with a time resolution of 10 ms. These wavelengths, which correspond to methane absorption bands in the spectrum of Uranus, were chosen to enhance the signal-to-noise ratio of the data by discriminating against the background light from Uranus<sup>2</sup>. The immersion and emersion records contained many 'spikes' as were observed during occultations by Jupiter and Neptune<sup>8</sup>. A variable component of scattered moonlight, amounting to a few per cent of the unocculted stellar intensity, was removed from the light curves before analysis. Details of our observations are given elsewhere<sup>3,9</sup>.

The light curves were analysed by the inversion method of French *et al.*<sup>10</sup> to yield the number density,  $n(h)$ , pressure,  $p(h)$ , and scale height,  $H(h)$ , of the uranian atmosphere as a function of height  $h$  in the atmosphere. [Note that inversion of occultation light requires the validity of certain general assumptions; see refs 11–16.] The temperature  $T(h)$  was determined through the relation  $T(h) = \mu g H(h)/R$ , where  $\mu$  is the mean molecular weight of the atmosphere,  $g$  is the local gravitational acceleration and  $R$  is the universal gas constant. Here we have set  $g = 830 \text{ cm s}^{-2}$ , which corresponds to a rotation period of 24 h, and  $\mu = 2.2 \text{ g mol}^{-1}$ , which corresponds to an atmosphere of hydrogen and helium in their solar abundances. At these altitudes the concentration of methane would be much too low to significantly affect the mean molecular weight<sup>17</sup>.

The temperature–pressure relationships obtained from the immersion and emersion data for our 7,280 Å channel are

shown in Fig. 1. The shaded region in the upper part of each figure represents the initial temperature and its uncertainty obtained from the initial conditions that were used to begin the numerical inversion of the data. The temperature profiles terminate at high pressures (lower altitudes) when the light flux has become small enough for the uncertainty in the zero flux level to produce a significant error in the profiles. The error bars on the profiles are due to the effects of noise in the original light curves. The scatter of adjacent points is less than the length of the error bars because the photon noise in the light curve produces correlated errors in the profiles, as discussed by French and Elliot<sup>18</sup>.

The temperature profiles in Fig. 1 show peak-to-peak variations of 45 K for immersion and 35 K for emersion. The temperature variations at higher altitudes are probably an artefact of the inversion procedure<sup>18</sup>, so that the actual temperature variations may be somewhat less than shown in Fig. 1 (particularly for emersion). Hence the peak-to-peak variations of

**Fig. 1** Temperature–pressure relationships for the upper atmosphere of Uranus. The temperature of the upper atmosphere of Uranus is plotted against pressure for *a*, the immersion data and *b*, the emersion data. The mean temperature of each profile is about 100 K, which shows that Uranus has a temperature inversion between  $10^{-3}$  mbar and the  $10^{-2}$  mbar level probed by IR measurements, where the temperature is 58.5 K. Both profiles show wave-like temperature variations, which may be due to dynamical or photochemical processes. Nearby points differ by less than the calculated error bars because the photon noise in the original data produces correlated errors in the temperature–pressure relationships. (Data from KAO Ch. 2).

35–45 K must be considered as maximum values. However, we believe that a large component of these variations is real and indicates that the atmosphere of Uranus is not isothermal in this region for three reasons: (1) the same variations occur in the temperature profiles derived from all three of our photometric channels; (2) the variations are much larger than the error bars, indicating that they cannot be attributed to photon noise in the data; and (3) similar variations occur in the profiles obtained from the Cape Town data. The variations may be due to dynamical processes in the atmosphere or photochemical layering, as discussed below.

The temperature gradients are sub-adiabatic everywhere, although the gradient near  $p = 10^{-3}$  mbar is very close to the dry adiabatic gradient. The condensation boundaries for  $\text{CH}_4$ ,  $\text{NH}_3$  and  $\text{H}_2\text{O}$  all lie well to the left of the profile, if we assume that the ratio of the number densities of these molecules to the hydrogen number density is fixed at the saturation value of the temperature minimum at the 100-mbar pressure level.

The mean temperatures of the region probed by the occultation events, obtained by averaging the points in each profile,

are 109 K for immersion and 96 K for emersion. We also obtained mean temperatures of 122 K and 110 K by fitting a model occultation curve<sup>19</sup> for an isothermal atmosphere to the data, but prefer the mean temperatures obtained from the inversion profiles since the atmosphere is definitely not isothermal in this region. The higher temperature obtained from the immersion data may be due to the 'phase' of the temperature variations and not represent an actual difference between the mean temperatures that would be obtained for these two regions by averaging over a sufficiently long time or a larger altitude range. We note that immersion occurred just before sunrise at latitude 4.5° north and emersion occurred just after sunrise at latitude 18.1° south. The subsolar latitude at the time of the occultation was 51.0° north, and the phase angle was 2.4°.

Summarising our conclusions about the thermal structure of Uranus in the  $10^{-4}$ – $10^{-2}$  mbar region: (1) the mean temperature is about 100 K, (2) the atmosphere is not isothermal and (3) the temperature variations are larger in the region sampled by immersion than that sampled by the emersion event.

The mean temperature of 100 K at the occultation level is about 40 K higher than the IR temperature, implying that a temperature inversion occurs between the  $10^2$  and  $10^{-3}$  mbar levels. The cause of the inversion may be heating of the upper atmosphere by methane, as postulated for the models of Wallace<sup>20</sup>, however, his model temperatures are warmer than the temperatures found here. His 'saturated' model is in better agreement than his 'supersaturated' model. Another possible explanation for the temperature inversion is the dissipation of energy by dynamical processes, if these are the cause of the observed temperature variations. However, the problem with this mechanism is that the possible dynamical processes identified so far would heat the atmosphere to a temperature well above the observed value<sup>21</sup>.

**Table 1** Temperatures of Uranus and Neptune

	Uranus	Neptune
Mean distance from Sun	19.2 AU	30.1 AU
Effective temperature (IR, $p \sim 10^2$ mbar)	$58.5 \pm 2$ K (ref. 22)	$59.7 \pm 4$ K (ref. 22)
Occultation temperature ( $p \sim 10^{-3}$ mbar)	100 K	140 K (refs 25–27)
Heating mechanism at $p \sim 10^{-3}$ mbar	CH <sub>4</sub> (?) (ref. 20)	CH <sub>4</sub> (?) (ref. 20)
Temperature variations (peak-to-peak) at $p \sim 10^{-3}$ mbar	35–45 K*	5–25 K (refs 25, 26)*
Origin of temperature variations	? (ref. 21)	? (ref. 21)

\* Maximum value, see text for discussion

The thermal structure of Uranus is somewhat different from that of Neptune, as is shown by the summary of IR and occultation temperatures in Table 1. Both planets have nearly the same effective temperatures, and this has been interpreted as showing that Neptune radiates about 2.8 times the energy it receives for the Sun, while Uranus radiates no more than 1.23 times the energy than it receives<sup>22,23</sup>. If Uranus has any internal heat source at all, it must be a smaller fraction of the solar energy received than the internal heat sources of the other giant planets<sup>23,24</sup>. The temperature inversion between the regions probed by IR and occultation measurements is much greater for Neptune than for Uranus. This is consistent with the conclusions of Gillett and Rieke<sup>17</sup>, who found a stronger temperature inversion for Neptune on the basis of methane and ethane emission at 8 and 12  $\mu$ m.

Both planets show temperature variations in the region probed by occultations. However, the cause of the variable temperatures and their relationship to radiative processes occurring in the upper atmospheres of these planets remain unknown.

We thank C. M. Gillespie, Jr and the crew of the Kuiper Airborne Observatory for their assistance and cooperation, and

P. J. Gierasch and R. G. French for discussions. This work was supported in part by grants from NASA and NSF.

## Electric currents in power transmission line induced by auroral activity

SURGES of electric currents induced by auroral activity were first observed in the middle of the last century in the wires of the electric telegraph<sup>1,2</sup>. In more recent years, auroral effects on long conductors, such as electric power transmission systems, telephone cables and oil pipelines, have attracted much attention because of various problems caused by these currents<sup>3</sup>. We report here measurements of the currents in a local power transmission line between Healy and Fairbanks and show that some of the fluctuations are aurorally induced.

The electric currents (induced by auroral activity) are caused by transient geomagnetic field variations which arise from concentrated ionospheric currents, called the auroral electrojets. Since the Earth is a spherical conductor, during intense auroral activity transient magnetic variations caused by the growth and decay or a rapid movement of the electrojet produce an induced Earth–surface potential. The induced potential in turn produces currents in a conductor, such as power, communication or pipeline systems, that are grounded to the Earth at two separate points<sup>4,5</sup>.

This induction effect is greatly complicated by various factors, such as the geometry of the conductor system with respect to the auroral electrojet and the geological structure in the vicinity of the conductors<sup>6</sup>. These effects are difficult to quantify in modelling the induction effect. Thus, to understand effects of the induced currents on powerline systems, the magnitude of the current must first be determined experimentally and the relationship between characteristics of geomagnetic variations and the induced currents in power line systems examined. However, no previous report has demonstrated clearly that some of the disturbances in power transmission lines are caused by auroral activity on the basis of simultaneous power line records and auroral activity records.

**Fig. 1** Comparison of the induced current in the Healy-Fairbanks power line transmission with the north-south component of the Earth current monitored in the same vicinity, and the **H** component magnetic records; 02.10 UT, 29 September, 1978 (16.24 AST, 28 September, 1978); AST, Alaska standard time.

**Fig. 2** As for Fig. 1; 10.19 UT, 29 September, 1978 (0.9 AST, 29 September, 1978).

We have therefore begun to monitor the induced current in a local power transmission line (138 kV, 100 A) in the vicinity of Fairbanks, Alaska, along a grounded neutral transmission line between Healy (the generator site) and Fairbanks, of length of 166 km.

Figures 1 and 2 show both the induced current in the Healy-Fairbanks transmission line at one of the transformer sites (substations) in Fairbanks. We show here the simultaneous **H** component magnetic record and the induced electric field (commonly referred to as 'the earth or telluric current') record taken in Fairbanks as indicators of auroral activity and the auroral electrojet. By comparing the induced current in the Healy-Fairbanks transmission line and the Earth current record it is obvious that the fluctuating currents in the transmission line were induced by the auroral induction. The corresponding negative excursions in the **H** component magnetic record indicate that auroral substorms were in progress during the intense indication events (see ref. 7 and note also that the induction at 03 UT was caused by the sudden commencement of the storm of 29-30 September, 1978).

In the Fairbanks area, multiple ground points exist, making the measurement of the total induced current difficult. By developing a model of the grounding network, however, we have been able to determine approximately the total current flowing in the Healy-Fairbanks line from our measurement at the substation. On the basis of our measurement and the model study, it is indicated that excursions of  $\pm 4$  A recorded at the substation would represent  $\pm 8$  A d.c. flowing in the transmission line.

The voltage and current induced in a transmission line are proportional to its length. In spite of the severity of magnetic disturbances in the auroral zone, the Healy-Fairbanks transmission line has escaped major troubles from the induction effects in the past because of its relatively short length. A transmission line across the auroral zone of length more than 500 km will require a careful design to overcome the difficulties caused by the induced currents.

We thank the personnel of Golden Valley Electric Association, Fairbanks, Alaska, for their cooperation in this study. The results reported here were supported by the ERDA Contract AT(45-1)2096, Task 5.

## Analysis for $^{15}\text{N}$ by proton scattering

STABLE isotopes have a great potential as tracers in the life sciences and environmental research, but their uses are still limited compared with those of radioisotopes. Radioisotopes have been widely used as trace elements, although there are problems in handling radioactive materials and preventing environmental contamination. The increasing concern about exposure to small amounts of radioactivity has caused us to consider the advantages of stable isotopes. The detection of stable isotopes, however, is not as sensitive as that for radioactive tracers and the preparation of a sample for use in stable

**Fig. 1** Typical spectrum of protons scattered by  $^{15}\text{N}$  in methionine-enriched 95% in  $^{15}\text{N}$ .  $^{15}\text{N}$ -methionine was suspended in the 1/20-diluted *Physarum* cell to  $5 \text{ mg ml}^{-1}$ . The target backing in a diameter of 12 mm was coated with  $5 \mu\text{l}$  of the specimen. The target was bombarded at 6.70 MeV with an exposure of  $37.9 \mu\text{C}$ .

isotope analysis is complicated. We have looked at the possibility of using a nuclear reaction caused by accelerated charged particles as a way of detecting stable isotopes. We have developed a system of stable isotope analysis using proton elastic scattering. Elastic scattering was chosen because the cross-sections are generally an order of magnitude larger than that of other reactions. Moreover, proton elastic scattering analysis has many advantages which are absolute, multi-element, rapid and subject to automatic data handling. Using this method an analysis for  $^{15}\text{N}$  has been done for biological studies. Nitrogen is an important component of various organic compounds which occur naturally but it has no long-lived radioactive isotopes. Here we outline the new system, and give an example of  $^{15}\text{N}$  analysis.

A system for  $^{15}\text{N}$ -labelled compounds has been developed using proton beams of the Tandem accelerator at the Research Center for Nuclear Science and Technology, the University of Tokyo. A clear peak of  $^{15}\text{N}$  in the energy dispersion of elastically scattered protons must be obtained for even a small quantity of the isotope. For this, an optimum experimental condition of incident energy, scattered angle, beam collimation, solid angle subtended by detector and pulse height analysis system, especially, pile-up rejection system must be found. Incident proton energies were selected on the basis of the excitation functions<sup>1,2</sup> of  $^{15}\text{N}(\text{p}, \text{p})^{15}\text{N}$  and of  $^{16}\text{O}(\text{p}, \text{p})^{16}\text{O}$ . Because  $^{16}\text{O}$  concentrations in natural biological samples are three orders of magnitude higher than that of  $^{15}\text{N}$ , the peak of the elastically scattered protons by  $^{16}\text{O}$  is too high and the tail of the  $^{16}\text{O}$  peak masks the peak of  $^{15}\text{N}$ . Thus, incident energies with low cross-sections for  $^{16}\text{O}(\text{p}, \text{p})^{16}\text{O}$  have been selected using the excitation function data<sup>2</sup>. In addition,  $^{15}\text{N}(\text{p}, \text{p})^{15}\text{N}$  excitation function was also compared to avoid undesirably low yield of the proton by  $^{15}\text{N}$ . We have therefore chosen several incident energies, 5.30, 5.82, 6.00, 6.30, 6.40 and 6.70 MeV, and have obtained spectra with test samples as described in the legend to Fig. 1. The incident energies of 5.82 and 6.70 MeV were selected because of a higher yield of the protons from  $^{15}\text{N}$  at 5.82 MeV and because of the clear separation of  $^{15}\text{N}$  peak from  $^{16}\text{O}$  at 6.70 MeV.

We used a scattering chamber with a Si solid-state detector as the detection system for elastic scattering protons. The detector was placed 191 mm away from the target and at  $165^\circ$  to the beam direction. Although an angle of  $180^\circ$  would be desirable for sufficient energy separation to resolve  $^{15}\text{N}$  peak from  $^{16}\text{O}$  peak, a scattering angle of  $165^\circ$  was selected because of geometrical limitation. The defining slit of the detector was 9 mm in diameter and the solid angle subtended by the detector was  $1.74 \times 10^{-3} \text{ sr}$ . To prevent background counts due to an

accumulation of proton pulses from  $^{12}\text{C}$  or  $^{13}\text{C}$  involved in backing materials, a 'pile-up inspector' was used. The scattered proton spectrum was recorded using a pulse height analyser. Backing material should not contain any element heavier than N, since protons scattered by heavier elements could easily result in increased background counts in lighter mass region. Thus, carbon foil, polyethylene and polypropylene films are chosen because of the thickness of available films and their constituent elements of carbon and hydrogen. Polyethylene films were normally used because they are thin (10  $\mu\text{m}$  thick), commercially available at a low cost, and samples can be easily spread on them.

Plasmodium of *Physarum polycephalum* were used for testing as it was being incubated in our laboratory<sup>3</sup>. Microplasmodia were incubated with semi-defined or synthetic medium<sup>4</sup>. The microplasmodia were collected by centrifugation, washed twice in water and diluted with water to a concentration of 1/20–1/10. The microplasmodia were then sonicated with an ultrasonic sonicator. The sonicated sample, volume 5–20  $\mu\text{l}$ , was dropped onto the backing by pipette, spread homogeneously on the backing material and dried.

Standard samples were prepared to compare yield ratios for the proton elastically scattered by  $^{15}\text{N}$  with respect to given concentrations of  $^{15}\text{N}$ -methionine. DL-methionine, enriched to 95% in  $^{15}\text{N}$ , was used. The  $^{15}\text{N}$ -methionine was suspended in sonicated microplasmodia which were prepared from culture on nutrient medium, and spread on polyethylene backings. Suspension in the sonicated microplasmodia was necessary because the methionine suspended in water could not be spread homogeneously onto the backing.

A typical spectrum is shown in Fig. 1. The peak of  $^{15}\text{N}$  was clearly separated from that of  $^{16}\text{O}$  or of  $^{14}\text{N}$ . The peak of  $^{32}\text{S}$  appeared clearly, which consisted of protons mainly from those in the methionine added. The spectra of  $^{12}\text{C}$  and  $^{13}\text{C}$  were dominated by protons from those isotopes in the polyethylene backing. The peak of  $^{14}\text{N}$  was due to protons mainly from  $^{14}\text{N}$  in crude lysate of the cell. The  $^{14}\text{N}$  counts were used as normalisation factor after the correction due to the contribution from  $^{14}\text{N}$  in the added methionine. Counting ratios of  $^{15}\text{N}/^{14}\text{N}$  are plotted as a function of  $^{15}\text{N}$  concentrations in Fig. 2. A linear relationship holds between  $^{15}\text{N}$  yields and added  $^{15}\text{N}$  concentrations.

Fig. 2 A linear relationship between proton yields and  $^{15}\text{N}$  concentrations.

An example of a proton spectrum for a sample containing  $^{15}\text{N}$ -labelled compound is shown in Fig. 3. The sample was prepared from microplasmodia of *Physarum*, which had been incubated in the defined medium<sup>4</sup> supplemented with  $^{15}\text{N}$ -methionine (95% in  $^{15}\text{N}$ ). Twice washed microplasmodia were sonicated and spread onto the polyethylene backing. The specimen was bombarded at 6.70 MeV with a total exposure of 59  $\mu\text{C}$ . The separated peaks of  $^{14}\text{N}$ ,  $^{15}\text{N}$  and  $^{16}\text{O}$  appeared clearly. Peaks corresponding to  $^{23}\text{Na} + ^{24}\text{Mg}$ ,  $^{31}\text{P} + ^{32}\text{S}$ ,  $^{35,37}\text{Cl}$  and  $^{39}\text{K} + ^{40}\text{Ca}$  are also discernible.

Fig. 3 Typical spectrum of protons by a bombardment of *Physarum* cell incubated with  $^{15}\text{N}$ -methionine.

The present method has advantages in that it can easily compare the abundance ratio of several elements and easily prepare samples. Even with a natural concentration of  $^{15}\text{N}$ , a peak of  $^{15}\text{N}$  was discernible and analyses for such samples are thought to be possible. However, to save time the solid angle of the detector must be increased. Further work is in progress to improve the system and to apply the system to the  $^{18}\text{O}$  analysis of biological samples.

We thank Dr Y. Yano for the preparation of the carbon foils.

## Evidence for the presence of Freon 21 in the atmosphere

MONITORING of trace constituents of the atmosphere is becoming increasingly important because of the implications on the quality of life of growing concentrations of several compounds which, after industrial use, are released to the atmosphere. In particular, concentrations of Freons and other halocarbons need to be checked because of the problem of ozone depletion<sup>1–4</sup>. Recently, the search for tropospheric sinks of Freons has been considered in connection with the controversy about withdrawing such compounds from the market. The hypothesis that F21 ( $\text{CHCl}_2\text{F}$ ), which has no industrial use and apparently is only produced as an impurity of F12 ( $\text{CCl}_2\text{F}_2$ ), could be a decomposition product of F11, has been made by several workers<sup>5,6</sup>. However, detection and quantitative analysis of this compound in the atmosphere is extremely difficult because: (1) it is present in extremely low concentration<sup>7</sup>; (2) gas

chromatography (GC) separation from other halocarbons is difficult<sup>8</sup>; (3) there are several interferences and sample contamination may easily occur. The presence of F21 in the atmosphere, although detected in several researches, is therefore still uncertain. Moreover, due to the sampling techniques used, which do not use strong sample concentration, to our knowledge no GC-mass spectrometry experiments have been reported. We report here the results obtained using GC-mass fragmentography for the analysis of F21 in atmospheric samples of country areas in the regions of Urbino and Rome.

The sampling technique, the elimination of artefacts due to impurities present in the carrier gas and trapping efficiency have been described elsewhere<sup>9</sup>. Between 5 and 20 l of air were passed through a stainless steel trap containing Carboxpack B, a graphitised carbon black (80–100 mesh), kept at the temperature of dry ice (about –90 °C), so that the break-through volume of F21 and other lighter halocarbons was higher than the amount of air sampled.

The GC was equipped with an oven where the trap was placed and heated to 200 °C. Injection into the column was by means of the heating-stripping technique, described elsewhere<sup>9</sup>.

Our major problem with the halocarbon analysis was to devise a suitable column to obtain a complete separation of all these compounds, for the reasons stated above. In particular, the separation of F21 from CH<sub>3</sub>I is important for the determination of the F21 concentration in the atmosphere. The column used for this purpose consists of Carboxpack B 80–100 mesh coated with 0.5% SP1000, a polar acidic liquid phase. This choice was made for two reasons. First, we use the outstanding selectivity of gas-liquid-solid chromatography, where the driving force of the chromatographic process is molecular polarisability, which in several cases is independent of the vapour pressure. Second, the modifications induced by rather low amounts of a polar liquid phase do not affect the selectivity towards non-polar compounds such as halocarbons.

Furthermore, by choosing an appropriate amount of liquid phase, the separation factors may be adjusted to the particular analysis required.

Rasmussen *et al.*<sup>9</sup> have reported the analysis of halocarbons trapped from 30 l of air in a suburban zone, showing that F21 is well separated from all the other halocarbons.

A major difficulty of quantitative analysis of halocarbons in the atmosphere is that some of these compounds are contained as ultra-trace impurities in high purity commercial gases. This problem has been solved by further purification of the carrier gas using a dry ice-acetone trap, and by purging the sampling traps with the purified gas before use.

Experiments have also been performed to see whether F21 could be an artefact due to sample treatment before GC analysis. A mixture of all C<sub>1</sub>–C<sub>2</sub> halocarbons except F21 was inserted in the trap and stripped at 170 °C. The resulting chromatogram did not show any peak with the retention time assigned to F21.

Mass fragmentography was performed using a VG/MM 305 mass spectrometer equipped with a jet separator and a data acquisition system.

Values of *m/e* 67, 69, 83, 85, 87, were monitored and the relative abundances of these fragments were found to be consistent with the mass spectrum of F21.

An accurate determination of the atmospheric concentration of F21 is not yet possible. However, it has been estimated to range between 10 and 20 p.p.t. v/v.

**Table 1** Relative concentration of F21 in the atmosphere of Rome and Urbino from GC data

Sample no.	Location	Sample vol (l)	Peak area (cm <sup>2</sup> )	Electrometer attenuation	Relative concentration
1, 2, 3, 4	Urbino	20	1.34	×512	1.00
5, 6, 7	Urbino	10	1.62	×256	1.20
8, 9, 10	Rome	10	1.20	×256	0.97
11, 12, 13	Rome	5	0.57	×256	0.85

**Fig. 1** Mass fragmentograms of a reference sample of F21 (a) and of the peak with the same retention time in an actual air sample (b). Computer output of the data. For details see text.

Table 1 shows the relative concentrations of F21 found in different samples from several locations. For each location the peak area is the arithmetic mean of the measurements made. Measurements within each location scatter about 20%, which is about the same as that found among measurements in different sites. Thus, it can be stated that, within the experimental errors, the concentration of F21 is fairly constant.

The computer output of the GC-MF analysis of one of the atmospheric samples is shown in Fig. 1: (a) refers to the standard F21 and (b) to the peak with the same retention time in an actual mixture of halocarbons trapped in the Urbino environment (20 l of air).

Fifteen samples trapped both in Rome and in Urbino have been analysed by GC-mass fragmentography and F21 was found to be present in each sample. The results of these experiments show that F21 is actually present in the atmosphere and cannot be considered as an experimental artefact.

This research was partially supported by EEC under contract no. 214-77-1 ENVI. We thank B. N. Green (VG Organic, Altrincham) and his staff for help with mass spectrometry.

## India and Madagascar in Gondwanaland based on matching Precambrian lineaments

THE geometrical fit of Madagascar against India has been widely accepted in most reconstructions of Gondwanaland<sup>1</sup>. This fit is consistent with Precambrian trends, lithologies and age provinces<sup>2,3</sup>. Palaeomagnetic data also support the general fit of Madagascar against India<sup>4</sup>, and there are suggestions that this reassembly can be recognised as far back as Proterozoic times<sup>5</sup>. The exact fit of east Madagascar and west India has not been adequately defined. Recent knowledge of the Precambrian geology and tectonics, has now allowed the possibility of better defining this fit, mainly on the basis of matching Precambrian re-entrant lineaments. The east coastline of Madagascar is a

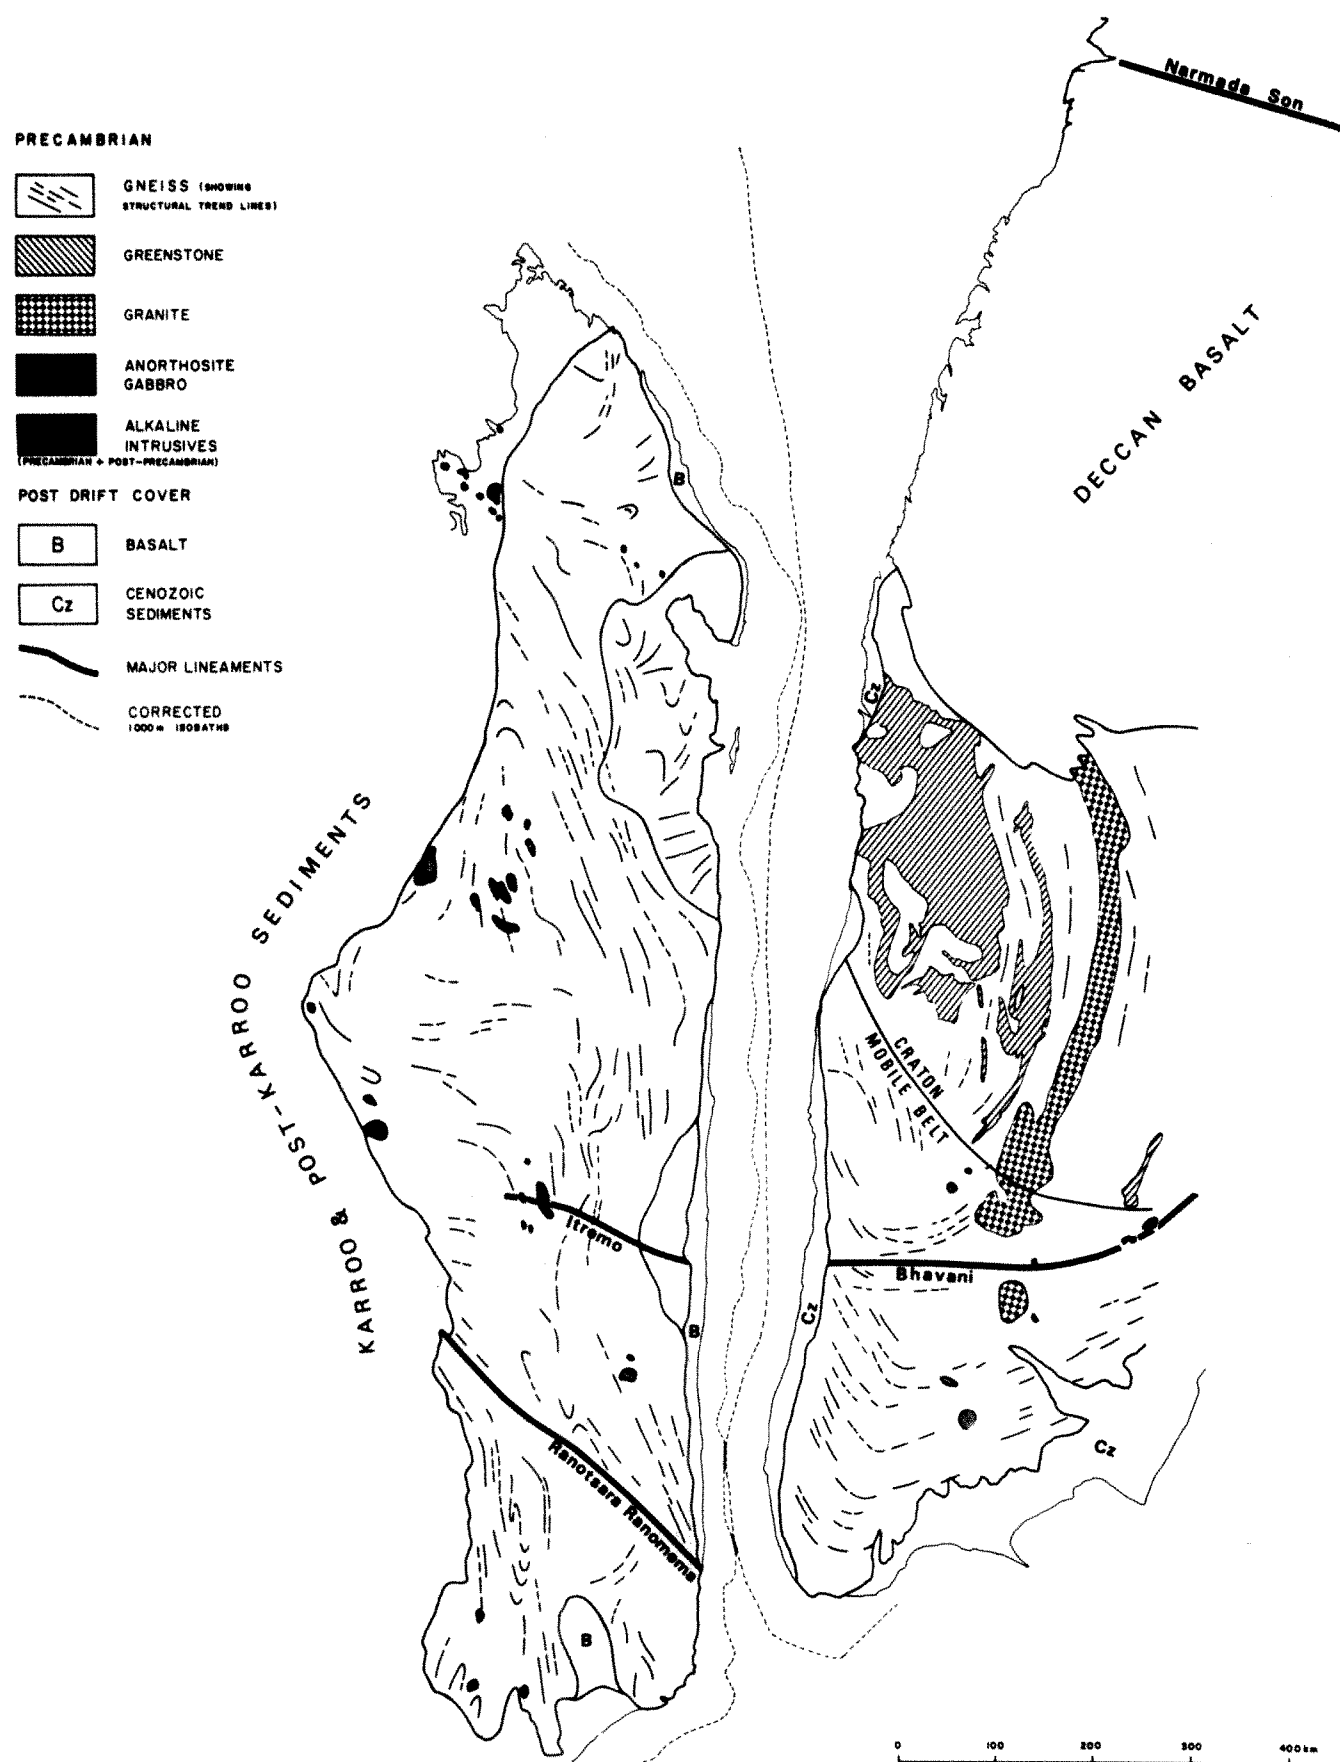

Fig. 1 India-Madagascar fit based on matching and Bhavani-Itremo lineaments. Areas in Madagascar outlined on the east coast are dated as Archaean and could possibly represent a craton.

rectilinear feature, with a narrow shelf of 25–50 km and an abrupt steep break in slope after the 1,000-m isobath. The proposed opposing coastline of west India is also rectilinear with a wider shelf of 100 km and a shelf break down to the 1,000-m isobath. The 1,000-m isobath of India was receded towards the coastline by removing the post drift sediments, according to the

best available sections<sup>6</sup>. A 1:2,500,000 conical projection was used to prepare a distortion-free, equidistance base map of both Madagascar and India (Fig. 1).

The Archaean terrain of south India consists of a craton, greenstone–gneiss complex surrounded by a charnockite mobile belt<sup>7</sup>. Basement gneisses have been dated as old as 3,200 Myr

**Fig. 2** India-Madagascar fit based on matching the Bhavani-Ranotsara-Ranomema lineament. The Narmada-Son lineament is continuous with a new lineament in northern Madagascar, shown here.

and old greenstones in the craton are about 3,000 Myr. Charnockite metamorphism in the mobile belt has been dated at about 2,800 Myr. Younger greenstones in the craton are about 2,600 Myr, and the granites have been dated at about 2,500 Myr. Proterozoic dates recorded in both the craton and mobile belt reflect later periodic events at about 2,000 Myr, 1,600 Myr and 900–600 Myr. The Archaean of Madagascar consists of the charnockitic complex of southern Madagascar, and a patchy distribution along the east coast<sup>8,9</sup>. The widely distributed Archaean dates suggest that most Precambrian Madagascar has an Archaean history. A strong Proterozoic overprint has masked this proposed widespread Archaean event. In contrast to India, no cratonic greenstone complexes are recognised and most of the rocks appear to belong to a charnockitic mobile belt<sup>8</sup>. The observation that the Indian craton is girdled by a charnockitic mobile belt seems substantiated by the evidence emerging from the proposed Madagascar–Indian relationships in Precambrian Gondwanaland. The only regional lithological correlations between south India and Madagascar are a charnockitic–gneiss mobile belt containing many anorthosite–gabbro bodies, that sweep around the southern and western margins of the Indian craton. The structural trend lines of the mobile belt recognised in south India can be traced into its equivalent in Madagascar<sup>2,3</sup> (Fig. 1).

From the economic viewpoint neither south India nor Madagascar are intensely mineralised. The paucity of mineral deposits recorded is not a conclusive indication of all overall poor mineral potential, as the tropical rain forest conditions and the rather attenuated exploration efforts in the past have undoubtedly contributed to a poor mining development. The metallogenesis of most of south India and Madagascar is restricted to silicates and oxides related to their common mobile belt tectonic setting. Similarly, the essentially gold–sulphide mineralisation of the Indian craton are not significantly represented in Madagascar. Several small mineral occurrences are known and occasionally exploited, and their consistence appears to be more than coincidental. Among the most obvious are the marine beach placers of monazite, zircon, ilmenite and rutile derived from the hinterland charnockitic massifs, the niobium–cerium mineralisation found associated with lineaments in Madagascar and south India, and the chromite, graphite, phlogopite and garnet occurrences.

Lineaments thought to penetrate the Indian–Madagascar parts of Gondwanaland have been used to define a fit<sup>10</sup>. The Narmada–Son lineament of northern India has been traced into northern Madagascar<sup>11</sup>. Other fundamental Precambrian lineaments recently described from south India and Madagascar can be utilised to define a more exact fit. In particular, the Bhavani lineament of south India<sup>12</sup> is compared to two important lineaments in Madagascar, the Itremo lineament of central Madagascar<sup>9,13</sup>, and the Ranotsara–Ranomena lineament of south Madagascar<sup>8</sup>. (Fig. 1). The fits described are compatible with the reconstruction models of Gondwanaland. The 1,000-m isobath of Madagascar is placed up against the receded 1,000-m isobath of India. This allows about 100 km of intervening continental shelf separating the opposing coastlines. Madagascar is translated relative to India along this line until the best fit is obtained in regard to geometry, bathymetry, age and lithological, structural and tectonic relationships. To define the tectonic line of reference, the Bhavani lineament was chosen. This lineament is a re-entrant feature from the Indian coastline and can be followed in a curvilinear trace to the north-east for about 500 km. The Bhavani lineament has been recognised as having an important role in the Precambrian tectonic evolution of south India<sup>12</sup>, and also controls the emplacement of alkali intrusives, including carbonatites and ultrabasics<sup>14</sup>. A similar lineament has been described from central Madagascar, here termed the Itremo lineament<sup>9,13</sup>. Several alkaline intrusions have also been recognised along the Itremo lineament. If the Itremo–Bhavani lineaments are matched, a penetrative, curvilinear feature can be traced across the Indian–Madagascar mobile belt (Fig. 1). Another possible fit is to match the Bhavani

lineament with a more distinctive lineament in south Madagascar, termed the Ranotsara–Ranomena lineament<sup>8</sup> (Fig. 2). The Ranotsara–Ranomena lineament is a major discontinuity separating the southern charnockitic block from the gneiss terrain to the north. The matching of the Bhavani–Ranotsara–Ranomena lineaments also satisfies many of the geological criteria set out above.

There is not yet enough information to establish, with certainty, which fit is best. If the Bhavani–Itremo fit is selected, it defines a major lineament which apparently controlled the emplacement of alkali intrusives and carbonatites. This fit also satisfies the geometrical and bathymetrical relationships. The Ranotsara–Ranomena lineament on extension into India can control continental margin features on the south coastline of India (Fig. 1). On the other hand, the Bhavani–Ranotsara–Ranomena fit also satisfies similar criteria. The Itremo lineament could still extend into India, as similar tectonic lines have been recognised from LANDSAT as re-entrants from the coast of west India<sup>15</sup>. In addition, the Narmada–Son lineament of northern India lines up with a new lineament recognised in northern Madagascar<sup>9</sup> (Fig. 2). Both of these reconstructions define major, penetrative curvilineaments that could have controlled small circle, prototransform directions in the Indian–Madagascar mobile belt, that contributed to the rifting of India from the Madagascar–African plate in Cretaceous times. The position of rifting also indicates possible control by the structural trends of the mobile belt and the presence of granulite facies charnockitic rocks<sup>16</sup>.

## Short-term climate change and New Zealand temperatures during the last millennium

MANY theories have been proposed to explain the climatic fluctuations which produced the sequence of glacial–interglacial periods of the order of tens of thousands of years which have occurred throughout the Quaternary. These fluctuations represent temperature changes in the temperate regions of about 6 °C between a glacial and an interglacial situation. There are also climatic fluctuations with a period of the order of about a thousand years representing temperature changes of about 2 °C. These changes are believed to have had an important bearing on human history, but have been little studied because it is difficult to obtain accurate temperature records for past

periods. Shorter temperature fluctuations of the order of a few decades, and representing temperature changes of perhaps as much as one degree, are of considerable economic importance and merge into the developing field of long-term meteorological forecasting. Considerable interest has recently developed in short-term climate changes. If detailed long-term climatic records could be obtained for extended periods in the past it might be possible to determine the causes for the climatic variation, and hence predict future climate trends. Even a knowledge of how hot/cold or dry/wet a particular region's climate could become, and with what probability, would be of considerable economic value to planners involved in hydro-electric development, irrigation schemes, snow clearance and the development of arid and polar regions. At present instrumental records have existed only since the mid-seventeenth century for central England, and for most other areas only over a little more than a century. Cave deposits (speleothems) provide stratigraphy which has a high inherent time resolution. Data for studying short-term temperature fluctuations can be obtained by measuring the  $^{18}\text{O}/^{16}\text{O}$  ratio of suitable stalagmites<sup>1</sup>. This technique should enable a high resolution temperature curve to be produced for many regions of the globe. We report here an investigation on the  $^{18}\text{O}/^{16}\text{O}$  profile through a New Zealand stalagmite which was undertaken partly to evaluate the feasibility of obtaining high time resolution data from speleothem material and partly to compare the temperature record from New Zealand (in the Southern Hemisphere and a region meteorologically unrelated to Europe) with the English climate curve, which is the most firmly established climate curve for the last millennium. Such proxy data given us the possibility of obtaining long-term high resolution temperature records from some of the critical regions of the world where meteorological records either do not exist or are of very short duration.

Long-term climatic fluctuations such as glacial-interglacial sequences have been studied by measuring the oxygen isotopic ratios in the carbonate from the foraminifera found in deep sea cores (see, for example, ref. 2). The movements of bottom living organisms and low sedimentation rates, however, limit the time resolution obtainable from most of these cores to about 3,000 yr. It may, however, be possible to carry out similar work in suitable regions of very high sedimentation rate and to obtain data for studies of short-term temperature fluctuations at least in more recent times.

Tree rings are another possibility for obtaining high resolution palaeoclimatic information (see, for example, ref. 3). Dendrochronology provides us with stratigraphic sequences, sometimes of considerable length, which can be obtained from many parts of the world. The bristlecone pine chronology from the White Mountains in California, for example, has a length of some seven millennia<sup>4</sup>. The isotopic-geochemical problems are formidable but a time resolution better than one year and absolute dating system accurate to one year could be obtained.

The work described here exploits the stratigraphy present in cave deposits where the chemistry is simple but the dating is less certain than with tree rings. It may eventually be possible to combine information from both sources and use the tree-ring record to confirm and correct the speleothem time scale.

If it can be assumed that a stalagmite has been laid down in isotopic equilibrium with the water then the oxygen isotope ratio of its calcite is controlled by two factors<sup>1</sup>: (1) the isotopic composition of the water flowing into the cave; and (2) the temperature at which the calcite is deposited on the speleothem, which for many caves can be taken as the mean annual temperature. The isotopic fractionation of the oxygen isotopes between calcite and water will increase by 0.024‰ as the temperature of deposition decreases by 1°C. As existing mass spectrometric techniques enable relative measurements of  $^{18}\text{O}/^{16}\text{O}$  to be made to 0.0025%, one should be able to obtain palaeotemperature curves to 0.1°C and this should be useful for studying short-term climatic fluctuations.

The  $^{18}\text{O}/^{16}\text{O}$  composition of the atmospheric precipitation percolating into the cave is determined first by the isotopic

composition of the oceans. This changes between the glacial and interglacial situation due to the removal of water depleted in  $^{18}\text{O}$  and its deposition on the ice sheets; however, this effect is negligible for the short-term temperature fluctuations in the present study. The second effect is caused by the temperature difference between the region of evaporation and the area under study. This effect tends to work in the opposite direction to the effect of temperature and hence would tend to reduce any fluctuations due to temperature. However, if tropical stalagmites are measured they should give temperature changes of the tropics directly. Further comparison between stalagmites from tropical and temperate regions will give a plot of changes in temperature differences during time and hence a record of past latitudinal temperature gradients. Such data could provide a measure of the intensity of the zonal atmospheric circulation in the past and throw light on such problems as loess deposition and sand dune formation and even provide interesting archaeological information.

Fig. 1  $^{14}\text{C}$  data from which the stalagmite was dated. Horizontal bars represent areas of the stalagmite sampled. Vertical bars represent  $\pm$  one standard deviation of the  $^{14}\text{C}$  determination.

Gathering any palaeoclimatic data from stratigraphy involves some dating method. In the case of speleothems this can be achieved for the past 35,000 years by  $^{14}\text{C}$  dating. However, the carbon laid down as carbonate on a stalagmite contains a mixture of ancient carbon from the limestone carbonate, which contains essentially no  $^{14}\text{C}$ , and modern carbon respired by plant roots. The calcium in solution has been dissolved from the limestone according to

Assuming that saturation is reached as the  $\text{CO}_2$  solution percolates through the limestone and into the cave then a little more than half the carbon in the resultant solution would be of recent biogenic origin and a little less than half derived from limestone<sup>5</sup>. This theoretical situation is not always the case (for example, the Twin Forks stalagmite). This is due to the exchange of carbon dioxide with cave air. Hendy<sup>5</sup> has described how such corrections can be made using  $^{13}\text{C}/^{12}\text{C}$  ratios. In the case of a stalagmite which is still growing when collected, an even more accurate estimate can be made by determining the  $^{14}\text{C}$  content of the outer layer of the stalagmite. Other methods such as thermoluminescence are also potentially useful for dating a material such as calcite. Several samples must be dated across the stalagmite to correct for any variation in growth rate of the stalagmite during the time under investigation.

We examined a stalagmite from a cave in north-west Nelson lat  $40^\circ 40' \text{S}$ , long  $172^\circ 26' \text{E}$  and growing at an altitude of about 50 m above sea level. The stalagmite was taken near a meteorological station which has a present-day mean temperature of  $12.2^\circ \text{C}$  (ref. 6). The stalagmite was sectioned and 30-g samples taken for  $^{14}\text{C}$  determination to provide a time base. These data are presented in Fig. 1. Samples ( $\sim 50 \text{ mg}$ ) were also taken at regular intervals down the axis of the stalagmite for isotopic analysis with a 1.6-mm steel drill. Five 10-mg aliquots of each of the samples of calcite were reacted with 100% phosphoric acid at  $25.0 \pm 0.1^\circ \text{C}$  in evacuated glass reaction vessels. The carbon dioxide was purified<sup>7</sup> and the ratios of mass

45 to (mass 44 + mass 46) and mass 46 to (mass 44 + mass 45) were compared with a sample of carbon dioxide prepared from Te Kuiti limestone<sup>8</sup> on a Nuclides Analysis Associates 60° double collector mass spectrometer. The  $^{18}\text{O}/^{16}\text{O}$  ratio is reported as  $\delta^{18}\text{O}$  with respect to the international standard PDB<sup>8</sup>, where

$$\delta^{18}\text{O}(\text{‰}) = \frac{^{18}\text{O}/^{16}\text{O}_{(\text{sample})} - ^{18}\text{O}/^{16}\text{O}_{(\text{PDB})}}{^{18}\text{O}/^{16}\text{O}_{(\text{PDB})}} \times 1,000$$

The mean values of the  $\delta^{18}\text{O}$  are plotted in Fig. 2, the error bars represent one standard deviation of each particular set of measurements. In such a study the  $^{13}\text{C}/^{12}\text{C}$  ratio must be plotted against the  $^{18}\text{O}/^{16}\text{O}$  ratio to ensure that they do not correlate and hence confirm that the stalagmite was laid down in conditions of isotopic equilibrium<sup>5</sup>. The results of these data are combined as a palaeotemperature curve on Fig. 3 and compared with Lamb's curve for central England<sup>9</sup>.

The curve has been scaled in terms of temperature as we know the temperature at which the stalagmite was growing when collected and the temperature change for the last cold period in New Zealand. This cold period occurred during the first decade of this century and was recorded by direct instrumental observations. As the above estimate agrees well with the known temperature dependence of the fractionation factor of calcite, it suggests that little or no change in the groundwater composition has taken place and the isotope fluctuations in the stalagmite studied seem to be mainly due to temperature changes.

These very preliminary results mainly investigate the potential of stalagmites to study short-term temperature variations. Clearly, many stalagmites should be taken from different caves in different parts of New Zealand. However, the temperature curve for New Zealand is apparently broadly similar to England and such climatic fluctuations as the Mediaeval Warm Period and Little Ice Age are not just a local European phenomenon.

It seems from the temperature curve that the cooling in New Zealand has been delayed and is generally more rapid than in central England. This may be caused by dating errors. The temperature is known better than the actual date of the New Zealand curve whereas the date is known accurately from historical records but the temperature may be in error for the English curve. However, the past 100 yr of the curve agree well with New Zealand meteorological records<sup>10</sup> and not the English temperature curve during the same period. Whereas the temperature of England since the 1940s has fallen significantly<sup>13</sup> the mean New Zealand temperature is still climbing<sup>10</sup>.

An interesting feature of the curve is that in recent times samples representing times as short as 10 yr were measured. Because the hole drilled in the stalagmite is circular in section more calcite is obtained from the central years of the time span

**Fig. 2**  $^{18}\text{O}/^{16}\text{O}$  profile through the stalagmite expressed in ‰ deviation from the international isotope standard PDB (Pee Dee Belemnite). The temperature scale on the left has been estimated using the modern day mean temperature for the region from which the stalagmite came and the known temperature fractionation of the calcite water system. The error bars represent one standard deviation of each particular set of measurements. The solid curve is the 50-yr running mean.

**Fig. 3** The 50-yr running mean curve (a) from Fig. 2 is compared with that from central England (b) given by Lamb, ref. 9.

with progressively less as the extremes are approached. A limiting factor to the time resolution of the technique is that winter precipitation is more depleted in  $^{18}\text{O}$  than summer precipitation. If there is more winter growth than summer or vice versa the point will be displaced upwards or downwards respectively. This effect only becomes significant when a small number of years is sampled. The problem could be overcome by drilling out many samples along a growth line and mixing them. However, this study shows that the technique is capable of a time resolution of only a few years and is apparently limited only by the winter/summer sampling problem. As can be seen from the New Zealand temperature curve, the very rapid temperature drop in the fourteenth century may well have had a catastrophic effect on the Polynesian agriculture, based as it was on the tropical food plants (taro and kumera) in all except the very north of the North Island. It is probably no coincidence that the Polynesian exploration of the South Pacific came to an end at this time. As has been discussed in an earlier paper<sup>14</sup> a cooling might be expected to lead to steeper latitudinal temperature gradients and hence to a more violent climate. The loss of travellers by the increase in frequency of more violent storms would effectively discourage further exploration.

We thank the New Zealand Institute of Nuclear Science for use of their mass spectrometer and for financial support to C.H.H.

## Effect of rapid precipitation of dissolved Mn in river water on estuarine Mn distributions

ALTHOUGH the general characteristics of estuarine chemical behaviour can be deduced from distributional data<sup>1</sup>, there is an urgent need for greater understanding of the mechanisms and kinetics of the processes involved to assist the development of precise geochemical cycling models and to allow accurate predictions of the consequences of waste disposal into estuaries and inland waters. Manganese is of particular importance in this respect because, as well as exhibiting pronounced reactivity within estuaries<sup>2-4</sup>, the highly absorptive properties of particulate and colloidal manganese oxide phases may contribute significantly to the estuarine behaviour of many other trace metals<sup>5</sup>. We show here how measurements of the effects of suspended particles and salinity on the rate of precipitation of dissolved manganese can lead to an explanation of the temporal and geographical variability in the distribution of dissolved manganese in an estuarine system.

During investigations of the distribution of manganese in the Tamar Estuary, South-west England, we have occasionally encountered a minimum in dissolved manganese (which can fall below  $1 \mu\text{g l}^{-1}$ ) in the freshwater immediately above the salt wedge. Such minima invariably coincide with high concentrations of suspended particulates produced by intrusion of the estuarine turbidity maximum into the freshwater. Upstream of the limit of this intrusion, dissolved manganese concentrations are usually within the range  $20\text{--}60 \mu\text{g l}^{-1}$ . These results indicate a rapid removal of dissolved manganese by the suspended particles. A study of this process has demonstrated zero-order reaction kinetics with respect to dissolved manganese in freshwater and has provided evidence of the mechanisms involved.

All experiments were carried out on samples of natural water obtained from the river and incubated in the dark at constant temperature. Dissolved manganese concentrations (passing a  $0.45 \mu\text{m}$  pore-sized membrane filter) were determined using the flameless atomic absorption procedure of McArthur<sup>6</sup> and the weight of suspended particulate material (dried at  $110^\circ\text{C}$ ) was measured gravimetrically. Experimental manipulation of suspended particulate concentration was achieved by mixing proportions of natural river water, collected either from within

or from upstream of the zone of maximum turbidity, with water which has been filtered through a  $0.45 \mu\text{m}$  membrane filter.

A rapid loss of dissolved manganese in natural river waters was obtained during these experiments which was kinetically of zero-order with respect to the concentration of dissolved manganese (see Fig. 1). In contrast, removal of dissolved manganese from estuarine waters approximated to first-order with respect to dissolved manganese and was considerably slower. The rate of removal decreased with increasing salinity. The zero-order rate law applied to samples of river water whether or not the particulate material originated from within the estuarine turbidity maximum, for particulate concentrations in the range  $0.5\text{--}500 \text{ p.p.m.}$ , and at temperatures within the range  $5\text{--}20^\circ\text{C}$ . Increasing temperature always accelerated the reaction. No detectable loss of manganese was apparent in samples from which the particulate materials were removed by filtration and the rate of removal increased with increasing particulate load. However, it was generally evident that lower particulate concentrations exerted a disproportionately large effect, particularly at higher temperatures. Furthermore, the rate of manganese removal varied significantly between experiments carried out at different times but with equivalent concentrations of particulate material. Using the Arrhenius equation to calculate the apparent activation energy of the removal process has consistently yielded low values, usually within the range  $5\text{--}15 \text{ kcal mol}^{-1}$ . The combined effects of temperature and the concentration of particulate material on the zero-order removal rate for a typical experiment are shown in Fig. 2.

Morgan's<sup>7</sup> extensive investigations would indicate that, for an oxidative reaction within an initially homogeneous solution corresponding in composition to the river waters under investigation, the reaction should, at first, proceed with first-order kinetics with respect to divalent manganese, but would be extremely slow. The oxidative reaction is, however, subject to pronounced autocatalysis generated by manganese oxide reaction products<sup>7,8</sup>. Other naturally-occurring particulate or colloidal surfaces, for example, silica<sup>9</sup>, feldspar<sup>10</sup>, hydrated aluminium and iron oxides<sup>5</sup>, seem to catalyse the oxidation although their catalysis may well be due to, or enhanced by, the presence of manganese oxide surface 'impurities'. Furthermore, manganese oxides, particularly if freshly precipitated, are highly efficient and to some extent specifically adsorptive and/or coprecipitative scavengers of certain metal ions, including divalent manganese<sup>11,12</sup>. Taking these properties into account, Crerar and Barnes<sup>13</sup> and Hem<sup>14,15</sup> have proposed that coupled specific adsorption-catalysed oxidation reactions occurring at the surface of pre-existing manganese oxide solids, with consequent regeneration of the reaction sites, can explain the continuous accretion of hydrogenous manganese oxide solid phases.

The kinetic results reported here are in accordance with such a mechanism. By analysing both dissolved and particulate manganese during a kinetic experiment, we have found that the reaction products are quantitatively retained by the particulate phase, although the kinetic results show that the catalytically effective property of the particles is conserved during the reaction. This agrees with the self-regenerating properties inherent in the mechanism noted above, and indicates that pre-existing manganese or mixed manganese-iron oxide phases occurring as superficial coatings on the particles act as self-maintaining catalytic sites for continued uptake of dissolved manganese. The indifference of reaction rate to the dissolved manganese concentration, that is zero-order kinetics, implies sorptive occupation of all available reaction sites by the reactant throughout the course of the reaction. This is possible if the rate of attainment of sorptive equilibrium for divalent manganese on the catalytic phase is considerably faster than the overall reaction rate. Experimental sorption studies<sup>11</sup> indicate that this is so. The slower, first-order reaction characteristic of estuarine waters can be attributed to a significant competition for occupation of the catalytic sites exerted by the major seawater cations.

**Fig. 1** Loss of manganese from solution in Tamar River water containing 0% (○); 10% (●); 50% (□); and 100% (■) of the original particulate load during incubation at  $5^\circ\text{C}$ . The water originally contained  $47 \mu\text{g l}^{-1}$  of dissolved manganese and  $60 \text{ p.p.m. (w/v)}$  suspended solids.

Fig. 2 Rate of zero-order loss ( $\mu\text{g l}^{-1} \text{d}^{-1}$ ) of dissolved manganese from solution in Tamar River water as a function of temperature and particulate load.

Temporal variations in the rate of manganese removal per mass of suspended particles are probably caused by an inherent natural variability in the surface characteristics of the particulates. The non-linearity of the relationship with respect to particulate concentrations at any one time is probably induced by increased aggregation of particles at higher concentrations of particulate material.

Although occurring within freshwater medium, the very rapid transfer of dissolved manganese to the particulate phase is an estuarine-induced phenomenon, in that the necessarily high concentrations of particles in the water column are generated and maintained by estuarine physical processes<sup>16</sup>. In the Tamar Estuary, cyclic spring-tide to neap-tide variability in the average amount of particulates comprising the turbidity maximum has been found to impart a corresponding variability in the rate and extent of removal of dissolved manganese in the freshwater immediately above the salt wedge. Furthermore, during neap-tide to spring-tide periods of increasing tidal amplitude, with pronounced net mobilisation of sediment, the removal of dissolved manganese may be more than counterbalanced by the infusion of sediment pore water containing relatively high concentrations of divalent manganese. Consequently the concentration of dissolved manganese in the freshwater entering the estuarine mixing sequence undergoes cyclic oscillation. This provides an alternative and/or complementary explanation for the common occurrence of a dissolved manganese maximum within estuarine water<sup>2-4,17,18</sup>. These maxima are usually attributed to desorption of manganese from riverine particles or to advective and diffusive influxes from the estuarine sediment although such explanations do not always seem to be quantitatively adequate<sup>2</sup>.

## Amino acids in interstitial waters of marine sediments

DISEQUILIBRIA within the mixture of organic matter, mineral particles and seawater in near-surface sediments result in extensive reaction, often biologically mediated. Variations in interstitial water composition are very sensitive indicators of the chemical and biological reactions in this zone of transition and the interaction between the water column and the permanent deposit<sup>1,2</sup>. Although most studies have been confined to inorganic ions, the few measurements of pore water DOC in marine sediments<sup>3-6</sup> show large gradients in dissolved organic matter concentration within sediments and across the sediment-water interface. We describe here our study of dissolved amino acids in interstitial waters, which were used to trace some of the biogeochemical processes affecting organic matter in marine sediments. We have analysed the dissolved free amino acids in 15 interstitial water samples from four cores obtained in Buzzards Bay, Massachusetts; the Gulf of Maine; and the North-west Atlantic continental rise. These pore waters have very high amino acid concentrations, of the order of  $1 \text{ mg l}^{-1}$ . In addition, the distribution of individual amino acids differs substantially from that reported for seawater<sup>7,8</sup>, particularly in the large relative abundance of glutamic acid and  $\beta$ -aminoglutaric acid.  $\beta$ -aminoglutaric acid ( $\text{HOOCCH}_2\text{CH}(\text{NH}_2)\text{CH}_2\text{COOH}$ ) is an isomer of glutamic acid which, to our knowledge, has not been previously reported in the marine environment.

Sampling was carried out using a 20 cm diameter sphincter corer<sup>9</sup> in Buzzards Bay and a 0.25 m<sup>2</sup> box corer (Sandia-Hessler Type MK III) in the Gulf of Maine and the North-west Atlantic. The Buzzards Bay (station P) sediment sampled was located in 17 m of water and was anoxic below the bioturbated upper 1-3 cm. Station 3 and station 8 in the Gulf of Maine were located at 250 m depth in the Wilkinson Basin and at 390 m in the Georges Basin, respectively. A small amount of  $\text{H}_2\text{S}$  was present in the deepest (24-28 cm) section at station 3, but none was detected in the 10 cm core from station 8. Station 10 was located on the continental rise east of the Gulf of Maine at a depth of 4,200 m. The sediment sampled was a strongly oxidising, foraminiferal ooze. Cores were sectioned immediately and the sediment subsamples refrigerated until squeezing was completed (within 24 h). Pore water was extracted from 100 to 200 g sediment using a hydraulically-powered stainless steel squeezer with two internal precombusted Reeve Angel<sup>(R)</sup> glass fibre filters and then refiltered through Gelman Type A<sup>(R)</sup> glass fibre filters (nominal particle diameter retained 0.3-1  $\mu\text{m}$ ). The filtered water and samples of whole sediment from corresponding core sections were frozen for onshore analysis.

After returning to Woods Hole, 10-20 ml pore water aliquots were applied to a 15 cm<sup>3</sup> Bio-Rad<sup>(R)</sup> AG 50W-X8 resin cation exchange column ( $\text{H}^+$  form) for desalting. The column was eluted with 25 ml water and then 1.5 M  $\text{NH}_4\text{OH}$  until the eluate began to become basic. The first 60 ml of the basic eluate containing the amino acids were collected, evaporated to dry-

**Fig. 1** *a*, Electron-impact ionisation mass spectrum of  $\beta$ -aminoglutaric acid from station 3, 0–2 cm core section interstitial water; SE-52 glass capillary GC column interfaced with a Finnigan GC-MS 3200, ionisation voltage 70 eV. *b*, Chemical ionisation mass spectrum of  $\beta$ -aminoglutaric acid; SE-52 glass capillary GC column interfaced with a Finnigan GC-MS 1015 SL,  $\text{CH}_4$  reactant gas, ionisation voltage 130 eV.

ness, and the residue derivatised to form the *N*-heptafluorobutyl *n*-butyl esters<sup>10</sup> for gas chromatographic (GC) analysis. Blanks of the entire analytical procedure, including rinses of the squeezer and filters, give negligible concentrations of amino acids.

Gas chromatographic analyses were carried out on a 32 m  $\times$  0.3 mm i.d. SE-54 glass capillary column. The column was installed in a HP 5840 gas chromatograph with splitless injection at a column temperature of 40 °C and an injector temperature of 225 °C. After four minutes, the temperature was increased at 30 °C min<sup>-1</sup> to 70 °C, and then at 3 °C min<sup>-1</sup> to 240 °C. The carrier gas flow rate was 2–3 ml He min<sup>-1</sup> and the FID temperature was 250 °C. Derivatives of cysteine, histidine, and tryptophan were not detected in these conditions, and asparagine and glutamine were measured as aspartic and glutamic acids, respectively. Selected samples were subjected to gas chromatography–mass spectrometry (GC-MS) (Finnigan GC-MS 3200 or Finnigan GC-MS 1015 SL). Compounds were identified by comparison to GC retention times and mass spectra of amino acid standards (Sigma) obtained in the same conditions and with the same instruments used for samples.

$\beta$ -Aminoglutaric acid (which may occur to some extent as the glutamine-isomer amide) is a major amino acid in our pore water samples, making up 2–50% of the dissolved free amino acids. The chemical ionisation (CI- $\text{CH}_4$ ) and electron-impact ionisation (EI) mass spectra of the interstitial water amino acid (as the *N*-heptafluorobutyl *n*-butyl ester) which we have identified as  $\beta$ -aminoglutaric acid are

given in Fig. 1. The molecular ion at  $m/e$  455 (confirmed by the presence of  $M+1=456$ ,  $M+29=484$ , and  $M+41=496$  in the CI- $\text{CH}_4$  spectrum) indicates that the compound is an isomer of glutamic acid. The greater intensity of  $m/e$  353 ( $=M-102$ ) relative to  $m/e$  354 is characteristic of a  $\beta$ -amino acid rather than an  $\alpha$ -amino acid<sup>11</sup>. The  $m/e$  326 ion (probable structure  $\text{C}_4\text{H}_9\text{OOCCH}=\text{NHCOC}_3\text{F}_7$ ) may arise subsequent to a rearrangement of the  $m/e$  353 ion

The base peak at  $m/e$  113 probably results from cleavage  $\beta$  to the amide N with loss of hydrogen:

The EI and CI- $\text{CH}_4$  mass spectra and glass capillary GC retention time of authentic  $\beta$ -aminoglutaric<sup>12</sup> acid are the same as those of the unknown compound in our samples. Those of the next most likely isomers of glutamic acid,  $\alpha$ -methylaspartic and  $\beta$ -methylaspartic acids, are markedly different.

Dissolved free amino acid concentrations in interstitial water are given in Table 1. Total concentrations in the samples analysed, ranging from 0.82 to 5.6 mg l<sup>-1</sup>, are two orders of magnitude greater than those found in nearshore waters, 5–30  $\mu\text{g l}^{-1}$  (ref. 7) or in open ocean seawater, 0–4  $\mu\text{g l}^{-1}$  (ref. 8). Concentrations generally reach a maximum within the upper 6 cm and then decrease with depth. Glutamic and  $\beta$ -aminoglutaric acids make up more than 90% of the dissolved free amino acids in station P interstitial waters, and from 76 to 90%

**Fig. 2**  $R$  ( $\beta$ -aminoglutaric acid/glutamic acid ratio): variation with depth in sediment and with overlying water column depth. ●, Station P (17 m); ○, station 3 (250 m); ▲, station 8 (390 m); △, station 10 (4,205 m).

of the total at station 3. Station 8 pore waters have significantly greater concentrations of other amino acids, especially alanine, glycine and serine, relative to glutamic and  $\beta$ -aminoglutaric acids which make up 40–75% of the total. Station 10 has a more uniform distribution of the protein amino acids and lower relative abundances of glutamic and  $\beta$ -aminoglutaric acids (18–35%).

Surface sediments from stations 3, 8, and 10 were hydrolysed in 6M HCl and the amino acids were analysed as described above. Concentrations range from 1.3 to 5.6 mg per g dry weight (Table 1), decreasing with overlying water column depth. The

\* Interstitial water dissolved free amino acid concentrations in  $\mu\text{g l}^{-1}$ , with depth-interval totals in  $\text{mg l}^{-1}$ .

† Sediment hydrolysate concentrations in mg per g dry weight.

‡ Amino acid abbreviations are standard, except  $\beta\text{Glu} = \beta\text{-aminoglutaric acid}$ .§ Peak sometimes had shoulder or partially resolved component which may be  $\beta\text{-alanine}$ .

¶ Peak sometimes had shoulder or partially resolved component, probably due to small amounts of lysine.

¶  $<10 \mu\text{g l}^{-1}$  for interstitial water and  $<0.01 \text{ mg per g dry weight}$  for sediment hydrolysate. Some minor components, including hydroxyproline,  $\gamma\text{-aminobutyric acid}$ , ornithine and  $\alpha\text{-aminoadipic acid}$ , were omitted from this table.

amino acid compositions of the sediment hydrolysates are similar to those found by others for organic-rich near-shore sediments<sup>13–15</sup>.  $\beta\text{-Aminoglutaric acid}$  is present only in trace amounts ( $<0.4\%$  of the total hydrolysable amino acids), and glutamic acid makes up  $<10\%$  of the total. Thus, if pore water amino acids are supplied from detrital proteins in sediments, for example by bacterial proteolysis, either the process is selective for particular residues or proteins of very unusual composition, or the freed amino acids are further metabolised to produce the observed distribution.

The large relative abundance of glutamic acid in interstitial water may result from the following transamination which many organisms, including bacteria, carry out as a first step in the metabolism of some amino acids<sup>16,17</sup>:

Another potential source for dissolved free amino acids in interstitial water is excretion or loss of cellular fluids by higher benthic organisms. The magnitude and even the direction of the net flux of amino acids to and from benthic organisms such as polychaetes is the subject of some controversy<sup>18,19</sup>, and there is little information on the composition of these fluxes. Thus the significance of this source of amino acids cannot yet be evaluated.

The large relative abundance of  $\beta\text{-aminoglutaric acid}$  in pore waters is surprising, because we have been unable to find any reference to it as a natural product in the literature. In the 15 samples we have analysed so far, the  $\beta\text{-aminoglutaric acid}$  concentration is correlated ( $r = 0.81$ ) with the concentration of glutamic acid. In contrast, glycine, another abundant amino acid in some of our samples, shows no significant correlation. However, the levels of  $\beta\text{-aminoglutaric acid}$  do not depend solely on those of glutamic acid, as can be seen from Fig. 2, which plots the  $\beta\text{-aminoglutaric/glutamic acid ratio}$  ( $R$ ) in pore water against depth in core.  $R$  increases with depth in all four cores. Furthermore,  $R$  is non-zero in surface sediments, and this surface ratio decreases with increasing water depth from station P through stations 3 and 8 to station 10.

The concentration correlation between glutamic acid and  $\beta\text{-aminoglutaric acid}$  in pore water and the increase of  $R$  with depth in sediment suggests that  $\beta\text{-aminoglutaric acid}$  is being formed from glutamic acid. The fact that substantial amounts of  $\beta\text{-aminoglutaric acid}$  are present in surface sediments indicates that the reaction proceeds very rapidly and is probably biologically mediated. However, we have found no indication that such an  $\alpha \rightarrow \beta$  isomerisation is carried out by bacteria or other organisms except during lysine fermentation by certain *Clostridia*<sup>17</sup>. On the other hand, the inputs of  $\beta\text{-aminoglutaric acid}$  and glutamic acid may be by separate, but related processes. The increase in  $R$  with depth in core might then be explained by preferential metabolism or reduced inputs of glutamic acid rather than its conversion to  $\beta\text{-aminoglutaric acid}$ . In either case the decrease in the surface  $R$  from the shallow to the deep-water sediments is probably related to some characteristic(s) of the sedimentary environments, for example, redox potential and the related nature of the benthic community metabolising organic matter. We are currently analysing additional samples from a wider range of sediment types to improve our understanding of the relationship between pore water amino acid concentration and composition and sedimentary environment.

This research was supported by Contract N00014-74-C0262 NR 083-004 from the Office of Naval Research and the Paul M. Fye Fellowship awarded through the WHOI Education Program to S.M.H. We thank Drs Nelson Frew and Philip Gschwend for obtaining mass spectra and Drs Cindy Lee, Robert Gagosian, Oliver Zafiriou, Fred Grassle and Werner Deuser for reviewing the manuscript. Authentic  $\beta\text{-aminoglutaric acid}$  was provided by Drs Alton Meister and Daniel Purich.

## Reduced thermogenesis in obesity

It is often claimed that there are obese patients who find it difficult to maintain a normal body weight because they have such low energy requirements that even normal intakes of energy result in weight gain and obesity. Studies of both children<sup>1</sup> and adults<sup>2</sup> show that there can be a twofold difference in energy intake between individuals despite apparently similar patterns of physical activity. An individual variability in the capacity to dissipate heat by metabolic changes has therefore been suggested<sup>3</sup> but no physiological basis for the differences in thermogenesis has yet been established. In genetically obese *ob/ob* mouse there are two components involved in the deposition of excess body fat: hyperphagia and increased metabolic efficiency<sup>4,5</sup>. Metabolic efficiency is the major factor responsible for obesity when the animals are kept at 20 °C so these animals provide a model study of the link between metabolic rate and obesity. Pre-obese and obese *ob/ob* animals have an abnormality of thermoregulatory thermogenesis with a reduced thermogenic response to cooling<sup>6</sup>. A defect in non-shivering thermogenesis can be confirmed by monitoring the thermogenic response to maximum doses of noradrenaline: the *ob/ob* mouse has only half the response of its lean littermate. The abnormal thermoregulatory thermogenesis quantitatively accounts for most of the metabolic efficiency of the obese animals as pair feeding at thermoneutrality rather than at 23 °C reduces the excess fat deposited by 65%<sup>7</sup>. We report here that obese adults with a family history of obesity have a reduced metabolic response to noradrenaline infusion compared with thin adults. As the reduced non-shivering thermogenesis is also found in subjects with familial obesity who remain at normal weight by persistent dieting, the defect in non-shivering thermogenesis appears to be constitutional and not a secondary consequence of obesity.

Thermogenic responses were tested in six obese women, aged  $47 \pm 4.5$  yr (mean  $\pm$  s.e.m.), who claimed to gain weight readily and who had a strong family history of obesity. A group of seven lean women of equivalent age ( $49.5 \pm 2$  yr), with no family history of obesity, served as controls. All seven claimed that they were able to eat freely and had no problems with weight gain. A third group of 'post-obese' women (aged  $44.2 \pm 5.4$  yr) was also studied once they had slimmed from an obese state after 1–2 yr on a severely restricted diet. They had maintained a stable weight by careful dieting for at least 3 months before the test. The subjects in all three groups were euthyroid and normotensive.

The metabolic capacity for thermogenesis was tested by infusing noradrenaline intravenously in a dose related to the ideal body weight (IBW). Tests were conducted at the same time

of year with all subjects in a weight-stable condition. Subjects were fasted overnight for 12 h and were tested in identical clothing in thermoneutral conditions (27.2–27.6 °C) after allowing 1 h for heat equilibration.

The resting metabolic rate (RMR) was measured at 1-min intervals for 30 min after the subject had rested supine for 30 min. Noradrenaline (Levophed, Winthrop) was then infused intravenously ( $0.1 \mu\text{g}$  per kg IBW per min) through a brachial vein for 45 min. The intravenous dose of noradrenaline was chosen to produce in the other arm a venous plasma noradrenaline corresponding to that found in moderately severe exercise. An indwelling Abbott 19-gauge venous cannula, kept patent with 3.8% sodium citrate (BPC) and inserted in the non-infused arm, was used to remove blood samples for assay. The RMR was measured continuously during the infusion and for 45 min after the infusion had stopped.

Immediately on starting the infusion of noradrenaline, the RMR increased and remained at near plateau levels for the duration of the infusion (Fig. 1). The rise in the RMR in the lean group was striking, amounting to an increase of 21.2%. In both the obese and post-obese subjects, however, the rise in RMR was only half that seen in the lean subjects, that is, 9.6% (Table 1). This difference in thermogenesis was seen despite the fact that similar rises in plasma noradrenaline were achieved in the three groups. Although the RMR in the lean group during the infusion was still less than that in the obese patients, similar metabolic rates were found during infusion in the lean and post-obese groups. The high pre-infusion RMR of the obese group was consistent with similar measurements made on other days and was therefore not due to stress but was related to their increased lean body mass<sup>8</sup>. The plasma adrenaline levels remained unchanged during the basal period and were similar in all three groups. There was also no increase in plasma adrenaline during the infusion, again indicating that stress played no part in the thermogenic differences.

During the infusion there was no significant difference between the groups in the rise of either the free fatty acids (FFA) or glucose (Table 1). However, the obese group showed a greater rise in the plasma glycerol and a marked increase in the insulin/glucose ratio, indicative of insulin resistance. As changes in plasma glycerol are considered a better index of changes in lipolysis than FFA responses, these results suggest that the lipolytic response to noradrenaline was greater in the obese. The

**Fig. 1** Absolute increase in RMR of women during and after a 45 min intravenous infusion of noradrenaline. ●, Lean; ○, obese; ▲, previously obese, now lean. RMR was measured by the ventilated hood technique using a Servo paramagnetic oxygen analyser and IR carbon dioxide analysis<sup>20</sup>. RMR measured by this technique agrees with direct calorimetry with a difference of 0.09%<sup>8</sup>. Values are means  $\pm$  s.e.m. Fully informed consent for the procedures was obtained and ethical approval was given by the unit's ethical committee.

Number of subjects given in parenthesis. Values are means ± s.e.m. Insulin to glucose ratio = insulin IU l<sup>-1</sup>/glucose mmol l<sup>-1</sup>. Significance values represent comparison of obese or post-obese with lean.

\* =  $P < 0.05$ ; \*\* =  $P < 0.02$ ; \*\*\*  $P < 0.01$ .

† Glucose rises during infusion and falls once infusion is stopped. However, insulin release is initially inhibited by the noradrenaline infusion but rises once the infusion is stopped—hence the ratio is measured again at the peak of the insulin response about 15 min after the infusion is stopped. Noradrenaline is measured by radioenzymatic assay<sup>18</sup>, FFA by titration<sup>19</sup>, glucose using a Beckman Autoanalyser, glycerol by an enzymatic assay system (Boehringer Mannheim no. 125032) and insulin by radioimmunoassay (Amersham kit no. 1M78).

defective heat production in the obese therefore cannot be explained by a subnormal rate of lipolysis. The equivalent FFA concentrations in all three groups also suggest that substrate availability for energy metabolism was not a factor in the different rates of thermogenesis. Issekutz *et al.*<sup>9</sup> have shown that the oxidation of FFA depends on the plasma concentration and that the relationship between plasma concentration and the rate of oxidation was the same in lean and obese subjects. A thermogenic system directly responsive to catecholamines therefore seems to be involved. The noradrenaline concentrations at the site of thermogenesis cannot be ascertained from this study but the markedly increased and equivalent venous noradrenaline levels in the three groups during the infusion and the similar metabolic response to noradrenaline found in this study compared with that observed previously in cold-adapted man<sup>10</sup> infused with noradrenaline at 150% of the rate used in our study, suggest that we were close to if not at the limits of the non-shivering thermogenic capacity of all three groups.

The difference between the lean and obese groups in the thermogenic action of noradrenaline is strikingly similar to that seen in genetically obese rodents with their defects in thermoregulatory thermogenesis.<sup>6</sup> In adult rats it is now evident that the process of non-shivering thermogenesis is dependent on the continued capacity of brown fat in the thoracic, cervical and subscapular areas to generate heat by mechanisms responsive to noradrenaline<sup>11</sup>. The metabolic activity of brown fat when stimulated is far in excess of that expected on a weight basis. Abnormalities of mitochondrial function have recently been reported in the brown fat of *ob/ob* mice<sup>12</sup>, but these abnormalities may be secondary to changes in the hypothalamus<sup>13</sup> as the thermoregulatory system of these animals is controlled so that body temperature is maintained approximately 2 °C below their lean littermates throughout the diurnal temperature cycle and at environmental temperatures varying from 10 to 25 °C (ref. 5). Below 10 °C, however, the *ob/ob* mouse becomes very hypothermic.

Our studies suggest that a similar mechanism may be involved in adult human subjects, as brown fat has been identified even in elderly men and women<sup>14</sup>. The defective thermogenic response of the obese women conforms with the reports of their enhanced susceptibility to body cooling<sup>15,16</sup> despite the additional insulation of subcutaneous fat. The defect in the women seems to be unrelated to energy intake, as two obese women who were deliberately fed 40 kcal per kg IBW per day for 7 days before testing responded to noradrenaline in a similar manner to that

after 3 weeks on a diet providing 9.2 kcal per kg IBW per day. Although an adaptive increase in the metabolic response to noradrenaline in man has been reported, the effect was observed only after exposure to prolonged and severe cold<sup>10</sup>.

We suggest, therefore, that the thermogenic abnormality in the obese women is constitutive rather than the result either of developmental or other environmental factors. If a direct relationship can be established between the thermogenic defect and metabolic efficiency in human subjects as well as in animals, then this test could prove to be a useful method for assessing the propensity to develop obesity in man.

We thank Mrs T. Saich and Mr G. Jennings for technical assistance and Dr Paul Trayhurn for helpful discussions. P.S.S. is in receipt of a Commonwealth Research Scholarship.

## Territorial behaviour of *Pemphigus* gall aphids

ALTHOUGH insects are known to defend nests, breeding sites and females<sup>1</sup>, the defence of feeding sites is less well documented. Other than the defence of egg clutches and nymphs by female treehoppers<sup>2</sup> and the existence of a soldier caste in woolly aphids<sup>3</sup>, territoriality has not been reported in the large insect order Homoptera which includes aphids, scale insects, hoppers, cicadas and whiteflies. As the evolution of territoriality is thought to be directly correlated with competition for resources in short supply<sup>4</sup>, territorial behaviour should only be exhibited when population densities approach the carrying capacity of the environment. Because parthenogenetic reproduction and the high population growth rates of aphids seem contradictory to the notion of limited resources, aphid territorial behaviour is not expected. I report here on the settling behaviour of the aphid, *Pemphigus betae* Doane, which forms galls of the leaf blade of narrowleaf cottonwood, *Populus angustifolia*. We have quantified the existence of a defended micro-territory, the production of a floater population of individuals displaced through competitive interactions, and the differential mortality of residents and floaters which favours the evolution of territorial behaviour.

Field observations and experiments were carried out in the springs of 1976 and 1978 near Ogden, Utah. As leaf buds begin to break in early spring, colonising stem mothers of *P. betae* emerge from overwintering eggs and migrate from the base of the tree to developing leaves. First instar stem mothers are black, about 0.6 mm long, and although wingless, are highly mobile. Within 4 or 5 days of arrival, most have settled and begun to methodically probe immature leaf tissues with their stylets to induce gall formation. Each stem mother is soon enclosed within a hollow gall where up to 300 progeny are produced parthenogenetically. Survival, number of progeny, and other measures of relative fitness are correlated with gall position on the leaf blade and mature leaf size<sup>5,6</sup>. When two or more stem mothers occupy the same leaf, they arrange themselves linearly along the midrib. Stem mothers occupying the base of large leaves achieve the greatest success, and these gall sites are highly preferred<sup>5,6</sup>.

When competitor densities exceed the number of superior gall sites available, territorial interactions occur during the brief colonisation phase before stem mothers become physically isolated by expanding leaf gall tissue. The outcome of these interactions is determined by kicking and shoving contests (Fig. 1) in which the largest stem mother usually wins or successfully defends a linear territory of about 3 mm at the base of the leaf blade. Body size was conservatively measured as the width of the semi-sclerotised prothorax. From microscope measurements of 54 pairs of first-instar competing stem mothers, the average prothorax width of basal stem mothers was 6.3% greater than that of their distal competitors (two-tailed paired *t* test,  $t = 3.298$ ,  $P < 0.005$ ). In agreement with these findings, Whitham<sup>6</sup> demonstrated that the removal of the defending basal stem mother can result in the downward shift of the remaining stem mother to occupy the superior basal position.

**Fig. 1** Typical back-to-back fighting posture of two competing stem mothers. The largest stem mother usually wins the superior basal position. Drawing by Pam Lungé.

**Fig. 2** Results of a 2-d contest in which the position of the subdominant distal stem mother is plotted as a function of the position of the dominant basal stem mother. Linear regression analysis ( $r = 0.934$ ,  $n = 88$ ,  $P < 0.001$ ,  $y = 1.17x + 0.28$ ) demonstrates that during contests, the position of each stem mother is based on the position of its competitor. Because stem mothers linearly arrange themselves along the midrib of the leaf blade, a single measure obtained with a caliper (the distance from the centre of each stem mother to a point marked at the base of the leaf) accurately quantifies position.

Contests can last 2 days and the basal stem mother can be displaced from her position. Figure 2 shows results from such a contest which began when a second stem mother arrived at an occupied leaf and displaced the resident to a suboptimal distal position. Positions were recorded every 10–15 min during daylight hours. During 44 of 88 recordings made, stem mothers were engaged in kicking and shoving contests in which no feeding or gall-forming activities occurred. The position of the subdominant distal stem mother on the leaf blade is plotted as a function of the position of the dominant basal stem mother. The high degree of correlation ( $r = 0.934$ ,  $P < 0.001$ ) indicates that stem mothers move like boxers in a ring, continually sparring to determine the winner. On the third day, only one stem mother remained. This example of an extended contest is unusually long for insects. Most observations of territorial contests have shown that the outcome is determined within a few minutes<sup>7–9</sup>. If contest time is evolutionarily determined, then contests lasting more than a few minutes suggest that great dividends or losses are at stake<sup>10</sup>.

Territorial interactions can produce a floater population of stem mothers searching for places to settle. Two adjacent trees differing greatly in the densities of competing stem mothers were selected for removal experiments. On one arm of selected Y-shaped twigs on both trees, all arriving stem mothers were removed every day for a period of 7 days; the control arm of each twig was sampled only on day 7. It was expected that on the high density tree where competitive pressures for limiting gall sites should be greatest, individuals of inferior competitive abilities would accumulate on removal twigs due to competitive release. In this case, the sum of all stem mothers removed would be greater than the number of stem mothers on control twigs. In comparison, on the low density tree, competitive pressures should be much reduced, enabling stem mothers to settle quickly without further movement. Consequently, few or no differences were expected in the settling patterns of stem mothers on removal or control twigs. On each tree approximately 2,500 leaves were examined. Figure 3 shows the pattern of stem

A basic question concerning applied research:

**Will your next research project establish the basis for developing an innovative product with significant commercial appeal?**

If your answer is an unqualified yes, you may be eligible for a

# TECHNICON RESEARCH GRANT

The Technicon Science Center in Tarrytown, New York, where Technicon Instruments Corporation, international leader in automated clinical analysis, conducts extensive research and development programs.

## THIS CAN MEAN:

- Research support of up to \$100,000 per year.
- Royalty payments on patents if Technicon is able to develop a marketable product following completion of the research.

## CATEGORIES

Following are examples of acceptable topics:

- Automated measurement of physiologic constituents, or medical diagnostic instruments generally.
- Non-invasive diagnosis of internal organs or measurement of physiologic functions.
- Detection of dental pathology.
- Veterinary diagnostic instruments.
- Instruments for industrial, agricultural or environmental measurement.

## WHO IS ELIGIBLE

Grants are available to scientists at colleges, universities, medical centers and non-profit research institutes in North American, Western European and Mediterranean countries.

## HOW TO PROCEED

Do not send a proposal at this time. Write to one of the following addresses for further information and a "Preliminary Submission Form." Deadline for full proposals is December 14, 1979.

In North America, write:  
Technicon Research Grants Program  
c/o Morris H. Shamos, Ph.D.  
Technicon Instruments Corporation  
Tarrytown, New York 10591

In Western Europe and the Mediterranean area, write:  
Technicon Research Grants Program  
c/o Harry W. Holy, Ph.D.  
Technicon International Division S.A.  
12-14 Chemin Rieu, 1208

# Swissair flies to 19 African cities

As you see, Swissair flies to so many African cities that by them you can pretty well recognize the outlines of the continent to which Swissair goes 47 times a week. So if you want to follow us around the continent you need only move clockwise from one of the 19 Swissair destinations to the next.

Swissair flies its DC-8s, DC-9s, and DC-10s (which, by the way, have only eight seats per row in Economy) every week to: **1** Casablanca (4 times), **2** Oran (twice), **3** Algiers (4 times), **4** Annaba (once), **5** Tunis (3 times), **6** Tripoli (3 times), **7** Cairo (6 times), **8** Khartoum (once), **9** Nairobi (twice), **10** Dares Salaam (once), **11** Johan-

**7**

**8**

**9**

**10**

**11**

nesburg (3 times), **12** Kinshasa (twice),  
**3** Libreville (once), **14** Douala (once),  
**5** Lagos (3 times), **16** Accra (3 times),  
**7** Abidjan (twice), **18** Monrovia (twice),  
 and **19** Dakar (3 times).

The fact that you can recognize whole  
 continents by its destinations is another  
 way to recognize Swissair.

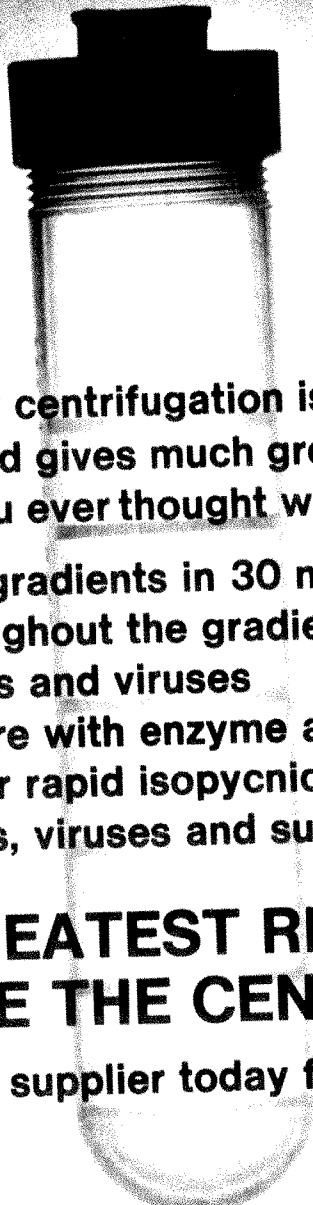

Winter timetable 1978/79, subject to change.

*Your IATA travel agency or Swissair will  
 be glad to give you all further information;  
 for instance about the best connecting  
 flights via Switzerland.*

**swissair.** 

# MIX AND SPIN PERCOLL™

 DENSITY  
MARKER  
BEADS  
NOW AVAILABLE  
for calibration of gradients of Percoll

Now centrifugation is simpler,  
quicker and gives much greater resolution  
than you ever thought was possible.

- Self-generating gradients in 30 minutes or less
- Isoosmotic throughout the gradient
- Non-toxic to cells and viruses
- Does not interfere with enzyme assays or quench radioactivity
- Low viscosity for rapid isopycnic or rate zonal separations
- Suitable for cells, viruses and subcellular particles

mother arrival on removal twigs. Of the 699 stem mothers attempting colonisation on the high density tree, 83% arrived over a 3-d period that peaked just after bud burst; on the low density tree, colonisation spanned the same time period but the peak was much reduced. Figure 3b, shows that when competitor densities are high, colonising stem mothers rapidly respond to the removal of competitors. The total number of stem mothers removed during seven consecutive days of sampling (535 per 1,000 leaves) was 69% greater than the number of stem mothers found on control leaves (316 per 1,000 leaves) ( $\chi^2 = 46.67$ ,  $P < 0.001$ ). On the tree with a low competitor density, however, the number of stem mothers collected on removal twigs (72 per 1,000 leaves) did not differ significantly from the number of stem mothers found on control leaves (61 per 1,000 leaves) ( $\chi^2 = 1.11$ ,  $P > 0.29$ ). The fact that there was a highly significant difference between treatment and control on the high density tree shows that stem mothers were moving in search of a place to settle and were reacting negatively to the presence of other stem mothers. On the other tree, however, densities of potential competitors were so low that competition for a limited number of gall sites was reduced, enabling all stem mothers to rapidly select leaves and immediately settle. Thus, with high population densities, many stem mothers are displaced through competitive interactions and a floater population is produced. These results are similar to those obtained in other systems as diverse as birds, mammals and fish, where subdominants or floaters moved into vacated spaces<sup>11-17</sup>.

Experiments indicate that the floater population suffers much greater mortality than the resident population. Before all stem mothers had permanently settled during colonisation, the positions of 211 stem mothers distributed among 351 leaves of a small branch were recorded. A sticky barrier (Tanglefoot) was placed at the base of the branch to prevent further recruitment. After all stem mothers had permanently settled, their positions were again recorded. Forty stem mothers had abandoned the positions they had held during the first census and attempted gall formation on other leaves. Of these individuals, only 24% survived, while 72% of those that did not move from their original positions survived ( $\chi^2 = 21.45$ ,  $P < 0.001$ ). This experiment has been repeated with another *Pemphigus* species and the results were identical<sup>5</sup>. Such differential mortality could be an important factor in the evolution of territorial behaviour and may account for the observed extended contest of Fig. 2.

The Eriosomatidae, or gall-making aphids of which *Pemphigus* is a member, exhibit a unique reproductive trait in which each stem mother is the sole progeny of a female sexual<sup>18</sup>. As

no other aphid group or known animal lays only one egg throughout their lifespan, this trait must have evolved under rather severe and/or unusual circumstances. I suggest that the advantage large body size confers in territorial interactions may have contributed to the evolution of this trait by favouring the reduction of clutch size and the placement of all resources into a single large egg.

I thank J. Alcock, H. R. Pulliam, C. C. Smith and W. V. Zucker for comments on the manuscript and acknowledge the support of NSF grant no. DEB 7905848.

**Fig. 3** Results of a removal experiment designed to test the hypothesis that due to territorial interactions occurring during leaf selection, a floater population is produced. Y-shaped twigs on two trees which differed in the density of competing stem mothers were selected. One arm of each twig acted as the control and was sampled only at the end of the experiment. On the other arm stem mothers were removed each day. *a*, Shows the number of stem mothers removed each day from both trees; *b*, compares the removal and control twigs for both trees (see text).

## Endomycorrhizal fungi and *Rhizobium* as biological fertilisers for *Medicago sativa* in normal cultivation

LEGUMES can form two types of symbiotic association with microorganisms. One, with *Rhizobium* sp., is involved in the fixation of atmospheric nitrogen; the other, with fungi of the family Endogonaceae that form vesicular-arbuscular (VA) endomycorrhizas, is concerned with the uptake of phosphorus by the plants. Glasshouse experiments have demonstrated that legumes inoculated with both types of microorganism grow and nodulate better, and have higher nitrogenase activity and phosphorus content than plants that are uninoculated or inoculated with either *Rhizobium* or mycorrhizal fungi separately<sup>1-12</sup>. Also, plants with both types of symbiosis may be important as pioneer colonisers of nutrient-deficient habitats<sup>13</sup>. At present, the possibility of field inoculation with mycorrhizas to improve yield, and the subsequent economy in the use of chemical fertilisers, are being considered<sup>14</sup>. Positive responses to VA mycorrhizas are to be expected mainly in soils low in nutrients, particularly phosphate, and where indigenous endophytes are sparse or inefficient<sup>14</sup>. Thus, the use of soil sterilisants to destroy indigenous endophytes has been assayed<sup>15-16</sup>. There are also reports on the effect of VA fungi inoculation in non-sterile soils<sup>17-20</sup>. The effects of endomycorrhizas on legumes in relation to the improvement of hill<sup>19-20</sup> and marginal soils are now being studied<sup>21</sup>. But as far as we know no data for leguminous crops growing on non-sterile arable soils in standard agricultural conditions in temperate regions have been published. We report here that inoculation of *Rhizobium* and *Glomus* improves the growth and nutrition of *Medicago sativa* in normal cultivation on an arable field.

The experiment was carried out on an irrigated calcareous soil (pH, 7.8) in a fertile valley ('vega') in Granada province, Spain. Its texture was: 25.2% sand, 30.0% loam and 44.8% clay. The soil contained 1,302 p.p.m. total N, 415 p.p.m. total K,

**Fig. 1** Effects of *Glomus* (G) and *Rhizobium* (R) on N, P and K uptake by *Medicago sativa* growing in an arable field soil under normal cultivation. Total N, P and K taken up by the plants is calculated from data of shoot dry weights and the percentage of element (mean of four replicates). Standard errors are shown.

611 p.p.m. total P, 9.2 p.p.m. available phosphate<sup>23</sup> and 1.74% organic matter. This field has been intensively cultivated for centuries and two crops per year are harvested. When the present experiment was designed the field had been left fallow for six months. Endogonaceae spores were recovered by the technique of wet sieving and decanting<sup>22</sup>. The number of spores per 100 g soil was:  $14 \pm 1.4$  yellow vacuolate<sup>24</sup> (*Glomus mosseae*<sup>25</sup>),  $2 \pm 0$  laminate<sup>24</sup> (*Glomus macrocarpus*<sup>25</sup>) and  $8 \pm 0.7$  unidentified. Spore numbers were, therefore, low but fall in the range of about 0.1–5 per g soil, recovered in most cases<sup>26</sup>. The predominance of *Glomus mosseae* spores in this field would justify, from the ecological point of view, the choice of this species as inoculant.

*Medicago sativa* L. cv. Aragón was the host plant for an endomycorrhizal fungus of the yellow-vacuolate spore type and for *Rhizobium meliloti* 203. Four seedbeds were prepared for plants for the field experiment. These were: uninoculated control (C), *Rhizobium*-inoculated (R), *Glomus*-inoculated (G) and *Rhizobium* + *Glomus* inoculated (R+G). The seedbeds were kept for 20 d in a glasshouse at 19–25°C. At this time, seedlings had a slight VA infection; about 3–5% of their root system. The experimental field was divided into four plots: C, R, G and R+G, to each of which seedlings from the corresponding seedbed were transplanted. Each plot consisted of four replicates with each replicate containing five 1 m<sup>2</sup> microplots. These microplots received 25 groups of three plants. Care was taken in selecting uniform seedlings and allowing some soil from the seedbed to adhere to their roots. Seedlings of R and R+G treatments were reinoculated with *Rhizobium* at transplanting.

**Table 1** Effects of *Glomus* and *Rhizobium* on the yield of *Medicago sativa* growing under normal cultivation in an arable field soil

Inoculation treatments	Shoot dry weight (g)
Uninoculated controls	15.18 ± 0.95
<i>Rhizobium</i>	15.94 ± 1.19
<i>Glomus</i>	22.56 ± 1.11
<i>Rhizobium</i> + <i>Glomus</i>	32.09 ± 1.77

Mean of four replicates.

Plants were irrigated by the farmers in their usual way, and no chemical fertilisers were applied during the experiment. At harvest, plants which grew during 12 weeks in the five microplots belonging to the same replicate were pooled, dry weights of shoots were recorded and analysed for P, N and K (ref. 27).

Table 1 records plant growth. It is clear that *Glomus* inoculation improved the yield of alfalfa, whereas *Rhizobium* inoculated alone did not. Uninoculated control plants showed nodulation by indigenous rhizobia, however, in *Glomus*-inoculated plants the introduction of *Rhizobium* was effective and plant dry weight was increased by nearly 50% (R+G treatment compared with G treatment). The available P content in the test soil is low; this probably not only determined the response of the plants to *Glomus* inoculation but also that plants not given a *Glomus* inoculum did not respond to *Rhizobium* inoculation. Phosphorus is known to be an essential element for N<sub>2</sub> fixation<sup>8,21</sup> and as it was a limiting factor in this experiment, plant growth and *Rhizobium* activity were not greater than for the uninoculated controls unless the plants were adequately mycorrhizal. *Glomus* inoculation improved total N, P and K uptake and the inoculation with *Rhizobium* was only effective when applied together with *Glomus* (Fig. 1).

The main conclusion from these results is that the mycorrhizal fungi *Glomus mosseae* is an effective 'biological fertiliser' for *Medicago sativa*. Inoculation with *Glomus* not only affected plant growth and nutrition but also enhanced the activity of *Rhizobium meliloti* when it was applied as inoculant. The introduction of *Rhizobium* together with *Glomus* and the subsequent establishment of effective dual symbiotic association with alfalfa was successful, as yield was increased by 211% compared with control. This suggests that it may be possible to reduce the chemical fertiliser inputs to this arable crop. This study may have practical significance for neutral-alkaline soils like the one used in the present investigation. As this soil is under intensive cultivation it has received, and is receiving, large amounts of organic and inorganic additives; as a result, the total P is high but the available P is quite low, probably because the added P fertiliser has become fixed, mostly by the calcium in this high pH soil, or by some minerals of the clay fraction<sup>28</sup>, which is relatively high in the test soil. The extensive use of fertilisers also accounts for the low number of Endogonaceae propagules<sup>29</sup>.

We thank Dr D. S. Hayman for criticism and corrections, Dr B. Mosse for providing mycorrhizal fungus, Dr J. L. García-Chicano and Chemistry Department, Zaidín, for some chemical analyses.

## Anomalous temperature dependence of the sodium conductance in rabbit nerve compared with frog nerve

THE sodium channel in excitable tissues is an integral component of the membrane, and is intimately associated with the surrounding lipid<sup>1</sup>. Thus, the electrophysiological parameters of the sodium channel might be expected to exhibit a characteristic dependence on temperature, reflecting the marked temperature sensitivity of the physical properties of most lipids. We report here voltage-clamp experiments which show that cooling a rabbit node below the region of about 6 °C does in fact sharply decrease the maximal sodium conductance, and markedly prolongs sodium inactivation. It thus seems that the lipid (or lipid-protein) environment of the sodium channel in the rabbit node undergoes a drastic change below 6 °C.

Single myelinated fibres from rabbit and frog (*Rana pipiens*) sciatic nerves were dissected and voltage-clamped<sup>2</sup>. The nerve chamber was initially allowed to stabilise at room temperature (25 °C). Pre-cooled liquid was then pumped through the brass block enclosing the nerve chamber, gradually cooling the whole preparation to about 0 °C in 15 min. The temperature was measured throughout the experiment by a small thermocouple (50 µm diameter) located about 1 mm beneath the node in the pool containing the node. A single fixed depolarisation to –20 mV (rabbit) or to –5 mV (frog), preceded by a hyperpolarising prepulse to –125 mV to remove sodium inactivation, was used to assay sodium conductance every 0.3–1 °C as the temperature fell from 25 to 0 °C. At the end of the experiment, the temperature dependence of the internodal resistance was measured over the same temperature range and used to correct for consequent changes in current. Typically, the internodal resistance increased progressively, rising by a factor of about 1.3 in both frog and rabbit nerve when the temperature fell by 10 °C. The net ionic current associated with the test pulse in a rabbit node consisted of an inward current superimposed on an outward leak current, potassium current being virtually absent in the mammalian node<sup>2,3</sup>. In frog nerve, tetraethyl-ammonium was added to block potassium current. After subtracting the leak component from the total ionic current, the values of  $\tau_h$  for both frog and rabbit nodes were determined by fitting the sodium current to the expression:

$$I_{Na} = G_1 e^{-t/\tau_h} (1 - e^{-t/\tau_m})^p$$

with  $p = 2$  for rabbit and  $p = 3$  for frog.

Figure 1 shows typical sodium current records from a frog and rabbit node of Ranvier at different temperatures. A 5 °C fall in temperature from 23 °C slowed the kinetics of the sodium

**Fig. 1** Sodium currents in a rabbit (a, c) and frog (b, d) node. Each pair of currents shows the response at a given temperature (23 or 6 °C) superimposed on one at a temperature 5 °C lower: a and b, 23–18 °C; c and d, 6–1 °C. In the rabbit  $E_{Na}$  was +70 mV at 25 °C and +65 mV at 0 °C; in the frog the corresponding values were +58 and +65 mV, respectively. The sodium current after leak subtraction and correction for temperature-dependent changes in the internodal resistance was calibrated by assuming a value of 10 mΩ for the internodal resistance at 25 °C. Note that the time to peak is increased relatively more in c than in a.

current in both frog and rabbit nerve by about the same extent and produced a similar decrease in the size of the current (Fig. 1a, b). However, a 5 °C fall in temperature from 6 °C produced a much bigger decrease in the peak current and a larger prolongation of sodium inactivation in the rabbit than in the frog (Fig. 1c, d). These effects of cooling were reversible on re-warming.

Figure 2 shows in greater detail the temperature dependence of the maximal sodium conductance,  $\bar{g}_{Na}$ , and the time constant of inactivation,  $\tau_h$ , for five rabbit and six frog nodes. The value of  $\bar{g}_{Na}$  was determined by extrapolating the decay phase of the sodium current back to the onset of the test pulse at each temperature. Figure 2 shows clearly that the curves for the temperature dependence of these parameters in frog and rabbit nodes have different shapes; in the frog the slope of the curve remains roughly constant over the whole temperature range<sup>4,5</sup>, whereas in the rabbit there is a marked change in slope at about 6 °C. Thus, the value of  $\tau_h$  for rabbit at –20 mV increased by a factor of about 1.73 for a 5 °C drop in temperature from above 15 °C ( $Q_{10}$  about 3), whereas below a transition temperature region (about 6 °C) the same drop in temperature increased  $\tau_h$  5.7-fold ( $Q_{10}$  about 33). Similarly, the values for  $\bar{g}_{Na}$ , which depended only moderately on temperature above 6 °C ( $Q_{10}$  about 1.7), became much more sensitive to temperature below 6 °C, the  $Q_{10}$  for the decrease being about 4.7. Because the rising phase of the sodium current was relatively fast, and because relatively few computer sampling points were taken during it, measurements of  $\tau_m$  were too uncertain for us to determine whether or not a similar discontinuity occurred with this parameter.

Several factors besides a reversible reduction of  $\bar{g}_{Na}$  could have caused the marked decrease of sodium current at low temperatures: for example, a reduction in  $E_{Na}$  or shifts of the  $h_{\infty}(E)$  and  $P_{Na}(E)$  curves with temperature. In the present study, the average values of  $E_{Na}$  at 25 °C and 0 °C were both 65 mV for frog nodes, and 65 mV and 60 mV, respectively, for rabbit nodes. A decrease of as much as 10 mV on cooling would have decreased the sodium current associated with the test pulse (at –20 or –5 mV) 1.2-fold at most. Furthermore, although the  $h_{\infty}(E)$  curves in both frog and rabbit were consistently shifted in the hyperpolarising direction (by 5–19 mV) when the temperature was lowered from 25 °C to 0 °C, this shift could not have contributed significantly to the observed decrease in sodium current because a large negative prepulse was used to remove any inactivation. Finally, any shift in the  $P_{Na}(E)$  curve was small

**Fig. 2** Arrhenius plot of maximal sodium conductance  $\bar{g}_{Na}$  (a) and of time constant of inactivation  $\tau_h$  (b) for frog and rabbit nodes. The data obtained from five rabbit and six frog nodes were normalised in each experiment by finding a least squares fit to the data points between 18 and 12°C and scaling all experimental points for that node so that the conductance at the mid-points of the lines (the expected value at 15°C) were 0.27  $\mu S$  and 0.25  $\mu S$  for the rabbit and the frog nodes, respectively, in panel a, and the corresponding times were 1.4 ms and 1.9 ms for the rabbit and the frog, respectively, in panel b. These values were chosen because they were the actual average values for  $\bar{g}_{Na}$  and  $\tau_h$  obtained experimentally. Each point is the average of 2–9 observations for  $\bar{g}_{Na}$  and 2–19 observations for  $\tau_h$ . The error bars drawn through each point ( $\pm 1$  s.e.m.) are usually smaller than the symbols. The rate of fibre rundown was slow compared with the rate of cooling and was not corrected for. However, rewarming took about 5 times as long leading to a hysteresis in the  $\bar{g}_{Na}$  but not the  $\tau_h$  curves. Two rewarming experiments are included in the mammalian  $\tau_h$  curve.

or absent ( $< \pm 10$  mV) and so could not have caused any substantial variation in current size with temperature since the test pulse of 60–75 mV was in the potential range in which the  $P_{Na}(E)$  curve had already reached a plateau, at both 25°C and 0°C.

The temperature-dependent transition reported here for the conductance of the sodium channel of mammalian myelinated nerve thus resembles the temperature-dependent transition already reported for the acetylcholine-activated channel conductance<sup>6,7</sup> and for other membrane proteins where activity, transport or mobility within the lipid have been assayed as a function of temperature<sup>1</sup>; it also resembles the transition found in frog nerve and muscle<sup>8</sup>. A change in membrane fluidity is thought to occur at these transition temperatures. It is possible that the same mechanism underlies the marked temperature dependence of the various functional parameters of sodium channel reported here for the rabbit node of Ranvier. Alternatively, a conformational change in the channel protein might

have occurred. The fact that there seems to be little or no discontinuity in the electrical parameters of the frog node of Ranvier in the present study may reflect species differences in the lipid composition of the membrane, or differences in the sodium channels themselves. Interestingly, in the rabbit nerve the transition temperature region is about the same for  $\tau_h$  and  $\bar{g}_{Na}$ , suggesting that the molecular structures regulating  $\bar{g}_{Na}$ , and those controlling the gating process, are surrounded by a similar lipid environment<sup>6</sup>. The nature of the marked reduction of  $\bar{g}_{Na}$  at low temperature is unclear; it may result either from a temperature-dependent block of the sodium channels or from a reduction in the single channel conductance. These alternatives might be distinguished by noise analysis experiments. If the transition temperature reported here is related to a phase change in the lipid surrounding the channel, then it might be possible to alter this temperature using agents that modify membrane fluidity.

We thank Dr J. V. Howarth for help in the construction and mounting of the thermocouple used in these experiments. We also thank Dr W. Schwartz who introduced us to the method of cooling. This work was supported in part by PHS grant NS 12327 and grant RG 981-A-1 from the US National Multiple Sclerosis Society.

## In vitro activation of a human macrophage-like cell line

SEVERAL permanent murine macrophage-like cell lines exhibiting various macrophage-associated effector functions have been described<sup>1–3</sup>, but establishment of permanent human macrophage cell lines has been much more difficult<sup>4</sup>. Recently Sundström and Nilsson<sup>5</sup> reported the establishment of a human histiocytic lymphoma cell line, U937, with macrophage characteristics. This line was further adapted to rapid growth *in vitro* by Lachman *et al.*<sup>6</sup>. During studies of major histocompatibility complex antigens on a number of human lymphoid cell lines we failed to detect Ia-like antigens (HLA-DR) on U937. Because these alloantigens have been reported to occur on early myeloid cells<sup>7</sup> and might therefore be regarded as differentiation antigens of stem cells, an attempt was made to produce differentiation and expression of new cell surface molecules on U937. Procedures similar to those used to produce differentiation of myeloid cell lines<sup>8</sup> and promote growth of macrophages in culture were tried. Although U937 cells failed to express Ia-like antigens they underwent remarkable morphological and functional changes. We report here that U937 can be activated by supernatants from human mixed lymphocyte cultures (MLC). Although this activation takes several forms, the findings reported here show marked augmentation of antibody-dependent cellular cytotoxicity (ADCC) against erythroid and tumour target cells.

Figure 1 presents photomicrographs of normal U937 (Fig. 1a) and activated U937 cells (Fig. 1b). Activation markedly alters

**Fig. 1** Cyto-centrifuge preparations of unactivated (a) and activated (b) U937 cells. Human macrophage-like line U937 was adapted to continuous growth in suspension culture independent of monolayer cells or their supernatants<sup>6</sup>. Generation time was 16–20 h. Unactivated cells (a) are grown in RPMI-1640 supplemented with 10% FCS. Activated cells (b) were cultured for 20 h in normal culture medium supplemented with 30% conditioned medium obtained in a one-way MLC on day 6 of culture. The CM used for the experiments presented in this paper used peripheral mononuclear cells from donor DS and an allogeneic B-cell line JoKo (irradiated) as stimulator. Wright stain,  $\times 672$  magnification.

the appearance of U937 cells: the cells become larger, the cytoplasm more vacuolated and the membrane more villous. In culture the activated cells are more adherent and have increased intensity of nonspecific esterase staining (not shown).

One of the principal functions of macrophages is their ability to mediate ADCC<sup>1–3</sup>. We therefore chose the ADCC assay to measure differences in activity of U937 macrophage-like cells. The ADCC data of five representative experiments are presented in Table 1. Unactivated U937 cells exhibited varying levels of ADCC activity against chicken red cell targets modified with TNP (CRC-TNP), as represented in the minimal levels of activity in experiments 1, 2, 4 and 5a, with higher levels in experiment 3. The reason for the fluctuating baseline ADCC levels of normal unactivated U937 is not clear. This variability may be caused by cell-cycle dependence of activity or 'nonspecific' activation by fetal calf serum (FCS) components. In contrast, U937 cultured with supernatants of human MLCs (conditioned medium, CM; see legend to Table 1), consistently showed increased activity in ADCC against CRC-TNP targets. This strong activity of activated U937 was not restricted to CRC-TNP targets; similar results were observed using sheep red cells modified with TNP (SRC-TNP) (Table 1, experiment 5b). Neither activated nor unactivated U937 were cytotoxic against

**Table 1** Antibody-dependent cellular cytotoxicity of activated U937 cell line against erythroid target cells

	CM	18.9	12.2	10.9	11.4

The effect of U937 activation on ADCC against erythroid target cells. ADCC was tested in a 2-h <sup>51</sup>Cr release assay against  $3 \times 10^4$  chicken red cells (CRC) or sheep red cells (SRC) modified with 2,4,6-trinitrobenzene sulphonic acid (TNP) and coated with rabbit anti-TNP antibodies, a method previously described<sup>1</sup>. The <sup>51</sup>Cr released in such an assay was due only to extracellular killing<sup>2</sup>. Assays were carried out in triplicate and s.e. did not exceed  $\pm 5\%$ . Spontaneous release of the targets in medium alone ranged between 0.5 and 2.0%. Since insignificant ADCC activity was shown by unactivated or activated U937 cells in the absence of anti-TNP antibodies, the results presented here show only the killing in the presence of anti-TNP antibodies.

\* Conditioned medium (CM) was obtained as described in Fig. 1.

† CM from irradiated JoKo (B-cell line) cultured alone.

‡ CM from peripheral mononuclear cells of individual DS cultured alone.

CRC-TNP or SRC-TNP in the absence of sensitising antibodies (data not shown).

To assess the extent to which product(s) of MLC supernatants were responsible for U937 activation, control experiments using supernatants of the responder cells or the irradiated stimulator cells of the MLC grown alone, were performed. Culturing U937 with CM from cultures of the responder alone (experiment 4—DS) or irradiated stimulator cells of the MLC (experiment 4—JoKo) resulted in low ADCC activity similar to that by unactivated cells (experiment 4).

The possibility that CM could enhance ADCC if present in the assay by a carry-over mechanism was also tested. CM added to

**Table 2** Phagocytosis of erythroid target cells by activated U937

Activating supernatant	Anti-TNP	% Phagocytosis

None	+	12.8	12.2	25.7	0.6	3.4
CM	–	7.9	10.5	7.7	–0.9	–0.8
CM	+	17.9	29.1	26.1	10.2	39.9

The effect of U937 activation on phagocytosis of erythroid target cells. Phagocytosis was determined by measuring <sup>51</sup>Cr of the endocytosed erythrocytes (CRC-TNP and SRC-TNP) by U937, according to the method of Walker and Demus<sup>2</sup>. The phagocytosis experiments presented here correspond to the ADCC experiments with the same number as shown in Table 1. Therefore, experiments 1, 2, 3 and 5a were done with CRC-TNP, whereas SRC-TNP were used for experiments 5b. The E:T ratio chosen for the phagocytosis experiments was 8:1. Groups without anti-TNP antibodies added represent Fc-independent phagocytosis, whereas groups with anti-TNP antibodies reflect Fc-dependent phagocytosis ('immune phagocytosis').

unactivated U937 cells during the 2-h ADCC assay, however, did not alter their activity (data not shown).

The activation of U937 is rapid. Enhanced ADCC against CRC-TNP was seen 6 h after addition of CM and reached a twofold increase after 28 h (Fig. 2a). In another study stimulation was measured as early as 3 h, reaching a peak after 3–5 d. Cultures fed with normal medium gradually lost activity after 3 weeks.

As ADCC is Fc receptor (FcR) dependent it was of interest to test whether activation of U937 correlated with FcR expression by these cells. A steady increase in the number of FcR+ cells was indeed detected by rosetting with antibody-coated erythrocytes (EA rosettes) as shown in Fig. 2b. A doubling in the number of FcR+ cells occurred during the first 28 h. By using aggregated  $^{125}$ I-IgG, as an independent measure of FcRs, a similar rising pattern was seen during activation. These data (not shown) clearly establish a direct relationship between the number of FcR+ cells in the activated U937 population and Fc-dependent phenomena such as ADCC.

Phagocytosis by activated U937 was enhanced in several experiments (Table 2, experiments 2, 5a and 5b) while in others (experiments 1 and 3) it did not exceed phagocytic levels of the unactivated U937. In all cases a greater percentage of target cells was phagocytosed when antibodies were present (antibody-dependent) than when they were absent (antibody-independent).

Although human peripheral blood monocytes have repeatedly been shown to mediate ADCC to several red cell targets<sup>9</sup>, their role in ADCC against tumour targets is controversial. Many studies suggest that antibody-coated tumour targets are killed by K cells<sup>10,11</sup>, whereas others ascribe this effector function to both K cells and macrophages<sup>12–14</sup>. Unactivated U937 cells have no ADCC activity against neoplastic cells. However, *in vitro* activation of the cell line as described in Fig. 1 resulted in significant and reproducible cytolysis of a variety of neoplastic cells (see Table 3). A wide spectrum of lymphoblastoid cell lines (LCL) and a myeloid line were lysed by activated U937 in a 4–6.5 h assay at effector:target ratios varying from 12.5:1 to 100:1. Target cells of human (HSB, MOLT4, SB and K562) and murine (EL4 and RL $\delta$ 1) origin with different surface characteristics were found to be sensitive targets.

**Fig. 2** Time kinetics of U937 activation and its effect on ADCC and FcR expression. *a*, ADCC of unactivated  $\square$  and activated  $\square$  U937 was measured in a 2-h  $^{51}$ Cr release assay against CRC-TNP (see Table 1). U937 cell line was activated with 30% CM and samples were tested after 3, 6, 9, 12, 21 and 28 h of cultivation. *b*, FcR+ cells in the activated U937 population  $\square$  were measured by their ability to form rosettes with ox red cells (ORC) sensitised with rabbit 7S anti-ORC antibodies. FcRs were expressed in 30–40% of unactivated U937 cells (data not shown).

**Table 3** Antibody-dependent cellular cytotoxicity of activated U937 against tumour target cells

Expt	E:T ratio	% Specific lysis

The effect of U937 activation on ADCC against nucleated tumour target cells. ADCC was tested in a 4–6.5 h  $^{51}$ Cr release assay against  $1 \times 10^4$  target cells TNP-modified and coated with anti-TNP antibodies as described above (see Table 1). Controls of unactivated U937 and cell mixtures in the absence of anti-TNP antibodies were negative and were therefore omitted. Activation was performed as described in Fig. 1.

\* HSB and MOLT 4 are leukaemic T-cell lines, SB is a B-cell line, and K562 is a myeloid leukaemia cell line.

† EL4 and RL $\delta$ 1 are T-cell lymphomas. All cell lines were carried as suspension cultures *in vitro*.

This study describes for the first time, the activation of a human macrophage-like cell line *in vitro*. U937 cells activated by supernatants of human MLCs exhibit a dramatic increase in their ADCC activity towards a variety of erythroid and nucleated-neoplastic targets. The activation is rapid and the marked morphological changes which occur are accompanied by an increase of FcR-bearing U937 macrophage-like cells. These results are in accordance with those of Shaw *et al.*<sup>13</sup> who have demonstrated ADCC activity by peripheral monocytes against nucleated target cells although McDonald *et al.*<sup>10</sup> and Nelson *et al.*<sup>11</sup> have reported activity mediated exclusively by K cells in their systems. The demonstration that a human macrophage-like cell line mediates ADCC against erythroid and neoplastic cells, and that this activity can be augmented, or in most cases induced in culture, will allow further investigation into the mechanism of activation and cytolysis by human macrophages. Biochemical studies of the activating molecule(s) are in progress.

## Specific depletion of alloreactive cytotoxic lymphocyte precursors

THE major barrier to replacement therapy in various clinical immunodeficiency states is the likelihood that the transferred immunocompetent T lymphocytes would react against alloantigens of the recipient and produce graft-versus-host (GVH) disease<sup>1</sup>. The logical resolution of this problem would be to delete or inactivate those clones of T cells which are specifically coded to react against the histocompatibility antigens of the recipient tissues. The remaining cell population could then fully reconstitute the recipient without danger of GVH reactions. Specific clonal deletion of this kind has been obtained in experimental animal situations by pre-circulation through a third-party host<sup>2,3</sup> or by induction of specific anti-idiotypic immunity<sup>4</sup>. These studies show the validity of this approach but are technically complicated and have limited application. A simpler method of obtaining this result has been sought based on the following strategy. To reconstitute a strain A mouse by transfer of lymphocytes from an allogeneic strain B, the strain B lymphocytes are first incubated on a monolayer of cells of strain A. Those clones which recognise the strain A alloantigens should adhere to the monolayer; the non-adherent populations of cells should now be unable to react against alloantigens of strain A but should still respond to alloantigens of other haplotypes. Although this kind of technique has been widely effective in removing fully activated cytotoxic lymphocytes (T<sub>c</sub>)<sup>5-9</sup>, its use to deplete alloreactive T<sub>c</sub> precursors has given variable results<sup>8,10-16</sup>. Significant depletion of precursors has been reported primarily when the non-adherent cells have been assayed *in vivo*<sup>13-16</sup>, but this has been claimed to be due to change in the responder cells, not depletion, as the same population assayed by *in vitro* generation of T<sub>c</sub> shows no evidence of depletion<sup>16</sup>. We present here a simple depletion method developed from our finding that when splenic lymphocytes are incubated for a few hours before being formed into a monolayer, they can effectively absorb alloreactive T<sub>c</sub> precursors even when assayed by the sensitive *in vitro* assays.

Figure 1 shows the results of experiments in which BALB/c responder cells were absorbed on monolayers of spleen cells constructed by attachment to Petri dishes coated with poly-L-lysine (PLL); the non-adherent responder cells were then

cultured with X-irradiated stimulator cells and after 5 d assayed for the presence of T<sub>c</sub>. Absorption on monolayers of fresh C57BL/10 (B10) spleen cells failed to reduce the BALB/c T<sub>c</sub> response to stimulation with B10 alloantigen (Fig. 1a), in agreement with reports of similar failures<sup>8,16</sup>. In contrast, absorption on monolayers constructed with B10 spleen cells which had been preincubated at 37 °C for 4 h abolished the response to B10 alloantigens (Fig. 1b). The specificity of the absorption is shown by the ability of the same population of non-adherent BALB/c cells to mount a normal T<sub>c</sub> response to B10.BR alloantigens, and further by the failure to deplete the response to B10 or B10.BR alloantigens when the absorbing monolayer was composed of preincubated BALB/c spleen cells (Fig. 1c). The latter experiment also demonstrates a consistent finding that absorption on a monolayer of preincubated cells commonly increases the T<sub>c</sub> response to haplotypes other than that of the absorbing monolayer, but this is not attributable to carry-over of monolayer cells. In this experiment, and those described below, the numbers of non-adherent cells recovered after incubation on the absorbing monolayer were consistently 97-102% of the number of responder cells applied, and by immunofluorescence tests with anti-H-2 antisera, cells of monolayer haplotype comprised only 3-6% of this population.

Table 1 shows that the technique is applicable to other strains. B10.BR spleen cells were specifically depleted of T<sub>c</sub> precursors

**Fig. 1** Effect of pre-incubation on the ability of splenic monolayers to deplete T<sub>c</sub> precursors. Monolayers for absorption were constructed by attaching  $\sim 2 \times 10^7$  spleen cells to polystyrene Petri dishes (50  $\times$  13 mm, Sterilin no. 122) previously coated with poly-L-lysine (Sigma)<sup>6</sup>. The spleen cells, prepared as previously described<sup>17</sup>, were used immediately or after 4 h incubation in 75-cm<sup>2</sup> flasks (Falcon no. 3024) containing 30 ml Eagle's minimum essential medium plus non-essential amino acids, supplemented with 10% v/v fetal calf serum (FCS) and  $7 \times 10^{-10}$  M 2-mercaptoethanol (MEM.FCS) at 37 °C with 10% CO<sub>2</sub> in air (pre-incubated spleen cells). The monolayers were washed twice in phosphate-buffered saline, overlaid with 2 ml of MEM.FCS and incubated for 5 min at room temperature before addition of responder cells ( $2 \times 10^7$ ) in 2 ml MEM.FCS. The dishes were centrifuged at 100g for 5 min in a prewarmed MSE Mistral 2L centrifuge and incubated for 1 h at 37 °C with 10% CO<sub>2</sub> in air. The non-adherent responder cells were recovered from the dishes by brief agitation, washed once, and  $2 \times 10^7$  resuspended in 9 ml MEM.FCS and transferred to a 25-cm<sup>2</sup> flask (Falcon no. 3013). Control cultures containing  $2 \times 10^7$  unfractionated responder cells in 9 ml MEM.FCS were similarly prepared. To each flask  $2 \times 10^7$  X-irradiated (1,000 R) B10 or B10.BR stimulator spleen cells were added in 1 ml MEM.FCS. All cultures were prepared in duplicate and incubated at 37 °C for 5 d with 10% CO<sub>2</sub> in air. Cytotoxicity was determined using a microassay previously described<sup>18</sup>. Duplicate cultures were pooled, washed and resuspended in 0.6 ml RPMI 1640 supplemented with 10% v/v FCS. All T<sub>c</sub> populations were titrated against <sup>51</sup>Cr-labelled tumour target cells of both stimulator haplotypes. The results obtained were expressed as % lysis  $\pm$  s.d. of triplicate determinations. Per cent specific lysis represents the % lysis minus the spontaneous release of label by target cells incubated with medium alone. Absorption of BALB/c (H-2<sup>d</sup>) responders on: a, fresh B10 (H-2<sup>b</sup>) monolayers; b, preincubated B10 monolayers; c, preincubated BALB/c monolayers. Comparison of the cytotoxicity generated against the homologous tumour target cell, when non-adherent responder cells were stimulated with B10 ( $\circ \cdots \circ$ ), or B10.BR (H-2<sup>k</sup>,  $\square \cdots \square$ ) as an unrelated haplotype, with unfractionated controls similarly stimulated (B10  $\bullet \cdots \bullet$ , B10.BR  $\blacksquare \cdots \blacksquare$ ). To eliminate any effect of storage of the responder cell populations during the 4-h preincubation of monolayer cells, a separate, fresh responder population was prepared for those experiments in b and c; hence, the unabsorbed control values differ slightly in a from those in b and c.

**Table 1** The ability of pre-incubated B10 and BALB/c monolayers specifically to deplete B10.BR T<sub>c</sub> precursors reactive towards H-2<sup>b</sup> or H-2<sup>d</sup> alloantigens

Responder	Pre-incubated monolayer	Stimulator	Cytotoxic titre H-2 <sup>b</sup> target	H-2 <sup>d</sup> target
B10.BR	—	B10	20.0	8.4
B10.BR	—	BALB/c	<1	55.7
B10.BR	B10	B10	<1	16.8
B10.BR	B10	BALB/c	<1	250.0
B10.BR	BALB/c	B10	50.1	5.0
B10.BR	BALB/c	BALB/c	<1	3.3

B10.BR responder cells were absorbed on monolayers of B10 or BALB/c preincubated spleen cells as described in Fig. 1. Non-adherent cells, or unfractionated responders as controls, were stimulated by either B10 or BALB/c alloantigen. The cytotoxic titre for a given T<sub>c</sub> population was calculated as the reciprocal of the highest dilution of the T<sub>c</sub> population which gave 15% specific lysis of the target concerned.

against H-2<sup>d</sup> or H-2<sup>b</sup> alloantigens by exposure to monolayers of preincubated BALB/c or B10 spleen cells, respectively. Similar results were obtained when CBA responder cells were used. The technique described thus seems applicable to several strain combinations.

Two further sets of experiments, by eliminating alternative explanations, strongly supported the suggestion that the results obtained are attributable to binding of T<sub>c</sub> precursors to the absorbing monolayer. First, 10<sup>7</sup> B10.BR cells which remained non-adherent after exposure to a monolayer of 4-h incubated B10 cells were added to an equal number of untreated, normal B10.BR spleen cells and cultured for 5 d with X-irradiated B10 stimulator cells. For comparison, a mixture of 10<sup>7</sup> X-irradiated and 10<sup>7</sup> normal B10.BR responder cells were cultured in the presence of X-irradiated B10 stimulator cells. Control cultures containing 10<sup>7</sup> non-adherent and 10<sup>7</sup> X-irradiated B10.BR responder cells were similarly stimulated. The results in Fig. 2 show that the non-adherent B10.BR cells did not significantly suppress ( $P > 0.3$ ) the response of normal B10.BR spleen cells to stimulation by B10 alloantigens. These results argue against the reduction in T<sub>c</sub> generation achieved by pre-exposure to an absorbing monolayer being attributable to induction of a suppressor population, or to blockage of the response by B10 cells or cell debris carried over from the monolayer.

Second, the reduction in T<sub>c</sub> generation is not due to depletion of a proliferative, helper population which has been claimed to be necessary for T<sub>c</sub> generation<sup>17</sup>. This was established by comparing <sup>3</sup>H-thymidine incorporation and T<sub>c</sub> generation of BALB/c cells which had been exposed to an absorbing monolayer of 4-h incubated B10 cells. The results in Table 2 show that, as expected, the non-adherent BALB/c cells were unable to mount a cytotoxic response when stimulated by B10 alloantigen but continued to show a normal T<sub>c</sub> response to B10.BR alloantigen. However, the proliferation of the non-adherent BALB/c cells in response to B10 stimulation has not been impaired; thus, the B10 monolayer has not depleted this responding, helper-type population. This result has been confirmed in four other experiments. The controls in this experiment show that the non-adherent cells show no significant proliferation in the absence of any added stimulus, implying that significant carry-over of B10 antigen or of B10 cells capable of proliferation (or stimulation) has not occurred. This agrees with the immunofluorescence tests cited above which showed only a very low release of monolayer cells. Further corroboration that our results are attributable to specific binding of the T<sub>c</sub> pre-

**Fig. 2** Failure of B10.BR responder cells, non-adherent to pre-incubated B10 monolayers, to suppress the cytotoxic response of normal, unfractionated B10.BR responder cells to B10 alloantigens. 10<sup>7</sup> B10.BR responder cells which remained non-adherent after exposure to a monolayer of 4-h incubated B10 cells, were added to an equal number of untreated, normal B10.BR spleen cells (■ · · · ■), and cultured for 5 d with X-irradiated B10 stimulator cells. Controls containing 10<sup>7</sup> X-irradiated (1,000 R) and an equal number of normal B10.BR responder cells (● · · · ●), and 10<sup>7</sup> non-adherent and 10<sup>7</sup> X-irradiated B10.BR responder cells, (□ · · · □) were similarly stimulated. Cytotoxicity was determined by titration of the T<sub>c</sub> populations against <sup>51</sup>Cr-labelled H-2<sup>b</sup> tumour target cells.

cursors by the absorbing monolayer comes from preliminary experiments in which T<sub>c</sub> against the monolayer haplotype were generated by culturing the adherent cells.

In conclusion, the method outlined here of absorption on a monolayer of preincubated lymphocytes gives extensive haplotype-specific depletion of T<sub>c</sub> precursors when subjected to the sensitive assay of *in vitro* induction of cytotoxic lymphocytes and has so far been successful in tests using various responder-stimulator combinations of eight mouse strains. The success of this method, in contrast to the variable results achieved in earlier reports, is due to the use of preincubated lymphocytes, which seem to form a more efficient absorbing monolayer. This could be due to a change in antigen presentation<sup>24</sup>, which increases the binding affinity of T<sub>c</sub> precursors, or to an increased binding of the absorbent monolayer cells to the PLL-plastic, preventing dislodgement of any complex of bound T<sub>c</sub> precursors and absorbing cell, or to a combination of both these factors.

Our results suggest two areas for further investigation. First, to define the change(s) induced by the pre-incubation of spleen cells that leads to effective T<sub>c</sub> precursor binding, and second, to investigate whether GVH activity is affected by the removal of T<sub>c</sub> precursors. However, the ability to deplete, and possibly recover, a population of T cells with restricted haplotype alloreactivity should be of immediate value in other areas of immunology, for example, in clarifying the role of major histocompatibility complex products in recognition by T cells<sup>21</sup>, or in evaluating the alternative models which have been proposed for alloreactive T-cell triggering<sup>22-24</sup>.

BALB/c responder cells were absorbed on monolayers of pre-incubated B10 spleen cells as described in Fig. 1. 10<sup>7</sup> Non-adherent cells, or 10<sup>7</sup> unfractionated responders as controls, were stimulated by 10<sup>7</sup> X-irradiated (1,000 R) B10, B10.BR or BALB/c stimulators, or none (nil), in 5 ml medium. To determine the proliferative response, duplicate 0.3-ml samples of each culture, after 3 d incubation, were transferred to a microtitre tray (Sterilin no. M29ARTL). Following centrifugation at 100g for 5 min, approximately half the supernatant was discarded and 25 µl of medium containing 0.5 µCi of <sup>3</sup>H-thymidine was added to each well. After incubation in a humidified box for 18 h with 10% CO<sub>2</sub> in air, cultures were transferred to microtubes and collected according to the method of Smart *et al.*<sup>20</sup>. Results obtained were expressed as <sup>3</sup>H c.p.m., and represent the mean ± s.d. of quadruplicate determinations. Cytotoxicity was determined as described in Fig. 1 after 5 d incubation.

## Reciprocal expansions of idiotypic and anti-idiotypic clones following antigen stimulation

It has been postulated by Jerne that a network of idiotypic and anti-idiotypic interactions between lymphocytes may constitute a principal form of immune regulation<sup>1,2</sup>. This network would control and 'remember' the antigen-induced activation of a particular (idiotypic) clone through its idiotypic or paratopic interactions with regulatory clones. These latter clones would in turn be regulated in the same fashion, creating what Jerne has called a 'web of V-domains' (ref. 2). Current experimental evidence strongly supports the concept of idio-type-directed regulation and also documents phenotypic complexity within the anti-idiotypic response; for example, anti-idiotypic cells (and/or their products) may help or suppress the idiotypic response<sup>3–8</sup>. However, this apparent complexity does not diminish the importance of Jerne's basic premise that reciprocal activation between idiotypic and anti-idiotypic clones could establish an equilibrium system capable of regulating the immune response<sup>9–11</sup>. We present here evidence for oscillatory behaviour in the population dynamics of a single, antigen-stimulated clone and for the reciprocal behaviour of the specific anti-idiotypic (idiotype binding) clones.

Our studies used the T-15/phosphorylcholine system in BALB/c mice. These mice, immunised with a vaccine of strain R36a *Streptococcus pneumoniae* (Pn), produce an essentially monoclonal, T-independent antibody response. The idiotype (T-15) of this anti-Pn antibody is shared with the myeloma protein secreted by the BALB/c plasmacytoma, TEPC-15. Both are specific for the hapten phosphorylcholine (PC)<sup>12</sup>. The kinetics and magnitude of the response of the T-15-bearing cells in the spleen was determined in two ways: (1) by the binding of radioactive [<sup>14</sup>C]PC and (2) by counting anti-Pn antibody plaque-forming cells (PFC) in agarose using R36a polysaccharide-coated sheep red blood cells (RBC) as indicator cells<sup>13</sup>. Both assays gave similar results; only the PFC numbers will be presented here. Serum antibody to Pn was measured by passive haemagglutination of antigen-coated sheep RBC. Changes in those clones recognising the T-15 idiotype (that is, the anti-idiotypic clones) were determined by the binding of the radiolabelled <sup>125</sup>I-myeloma protein, TEPC-15, on spleen cells. As a control, we used: (1) <sup>125</sup>I-MOPC-315 myeloma protein which has the same isotype (IgA) as TEPC-15 but which has both different idiotype and binding specificity; and, (2) <sup>125</sup>I-McPC-603, an IgA myeloma protein that binds PC but does not bear the T-15 idiotype<sup>14</sup>.

The time course of the idiotypic (T-15) and anti-idiotypic (T-15 binding) clonal responses after stimulation by Pn was visualised by the sequential immunisation of groups (3–4) of BALB/c mice (age- and sex-matched). Daily, for 14 d, a group of mice was immunised by an intraperitoneal injection of 20 µg of Pn vaccine. Thus, each group represented a unique stage of the anti-Pn response. On the 15th day, all immunised mice and a group of unimmunised mice were killed, and their spleens removed and disrupted into single cell suspensions. These cells

were washed three times in media and finally resuspended to a concentration of 10<sup>7</sup> viable lymphocytes per ml. Duplicate aliquots (10<sup>6</sup> cells in 0.1 ml) of these suspensions were then assayed as described above. This experimental schedule allowed mice at different stages of the anti-Pn response to be assayed simultaneously and using the same reagents. However, not more than three to four mice per interval could be handled. Therefore, to ensure the reproducibility of the data, we repeated the experiment four times, obtaining similar results in each trial.

As shown in Fig. 1, the accumulation of specific anti-Pn PFC in the spleen after a single injection of the antigen followed a cyclical pattern: a broad peak on day 5 (≈ 700 PFC per 10<sup>6</sup> splenocytes) was followed by a second, sharper peak on day 12 (≈ 200 PFC per 10<sup>6</sup> splenocytes). Specific binding of the hapten (PC) to the spleen cells coincided with the curve of the PFC, usually reaching a maximum 1 d before the PFC peak (data not shown). However, serum anti-Pn antibody titres did not reflect the cyclical pattern of splenic PFC; titres were highest around day 8 and then declined steadily.

The specific binding of <sup>125</sup>I-TEPC-15 by spleen cells from the immunised mice also underwent cyclical changes that seemed to be out of phase with the PFC curve (Fig. 1). Thus, the relative binding of T-15 (per cent of the control) rose to a maximum

**Fig. 1** Groups of three to five BALB/c mice were injected intraperitoneally with 20 µg of Pn vaccine at 2–14 d before removal of their spleens. Aliquots containing 10<sup>6</sup> viable splenic lymphocytes were assayed for anti-Pn PFC (▲) and specific binding of <sup>125</sup>I-TEPC-15 myeloma protein (●). Serum, collected at the time of splenectomy, was assayed for anti-Pn antibody by passive haemagglutination of antigen-coated sheep RBC (□). Each symbol represents the mean of four experiments (12–15 mice). The vertical bars indicate the range of those experiments. For determination of <sup>125</sup>I-TEPC-15 binding, ascitic fluid from BALB/c mice bearing the plasmacytomas TEPC-15, MOPC-315 or McPC-603 was recovered and purified by (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> precipitation and gel (Sephadex G-200) filtration. Each purified protein was tested for its capacity to haemagglutinate Pn- or TNP-coated sheep RBC. Iodination was with radioiodinated Bolton-Hunter reagent (NEN), 5 mg protein per mCi <sup>125</sup>I. Iodinated proteins were equivalent to non-labelled proteins in their ability to haemagglutinate. To determine the optimal concentration of radioligand, spleen cells from BALB/c mice injected with TEPC-15 protein<sup>19</sup> and then allowed to rest for 2 months were incubated with 10-fold dilutions of <sup>125</sup>I-TEPC-15 or <sup>125</sup>I-MOPC-315 0.1–100 µg protein. Saturation occurred at ≈ 1 µg for both proteins. Inhibition of binding (68–75%) occurred in the presence of 100 µg cold homologous ligand but not with the heterologous ligand or bovine serum albumin. To measure T-15 binding, duplicate tubes containing 10<sup>6</sup> cells in 0.1 ml of ice-cold Hank's balanced salt solution containing 2% FCS were incubated at 4 °C for 10–12 h with ≈ 1 µg (0.05 ml) of labelled TEPC-15, MOPC-315 or McPC-603. The cells were then washed three times in cold Hank's containing 10% FCS and the radioactivity of the cell pellet was determined as c.p.m. Variation within duplicates was routinely less than 15%. Specific TEPC-15 binding is defined as: (c.p.m. bound <sup>125</sup>I-TEPC-15) – (c.p.m. bound <sup>125</sup>I-MOPC-315 or <sup>125</sup>I-McPC-603). In any single experiment, specific TEPC-15 binding was computed by the subtraction of only one of the control proteins. Because the c.p.m. of bound MOPC-315 or McPC-603 remains constant (see text) throughout the 14-d experimental period, both serve equally well as specificity controls. The specific TEPC-15 binding is then expressed as per cent of binding by spleen cells from the control group of unimmunised mice (control = 100%).

**Table 1**  $^{125}$ I-TEPC-15 binding in the presence of excess McPC-603\*

	Time (days) after immunisation with Pn							
	0	3	4	6	8	9	10	12
T-15 + McPC-603	100	111	125	86	164	147	127	79
Average T-15 bound	100	190 (120–260)	150 (120–180)	74 (50–100)	110 (90–160)	115 (75–145)	160 (150–195)	90 (60–125)

\* Groups containing three age- and sex-matched BALB/c mice were immunised as described in the text. On day 0 mice were killed and from each group a suspension of pooled spleen cells was made in ice-cold RPMI-1640 media with HEPES buffer (pH 7.3). The cells were washed three times in fresh media and resuspended to a concentration of  $10^7$  viable lymphocytes per ml. Aliquots of 0.1 ml of the appropriate cell suspension were then added to duplicate tubes containing 3  $\mu$ g of  $^{125}$ I-TEPC-15 and 100  $\mu$ g of McPC-603. Cells were incubated overnight at 4 °C and then washed three times in Hank's balanced salt solution containing 10% fetal calf serum (FCS) (pH 7.2). The recovered cell pellets were then counted as described. Binding is expressed as per cent of the day 0 binding value. T-15 binding was measured as described in the text. Binding is expressed as per cent of the day 0 control and the range of four experiments is indicated in parentheses.

(two- to threefold) on day 3, declined steadily until day 6, and then increased to a second maximum by days 10–11, which immediately preceded the second PFC peak (day 12). T-15 binding fell on day 12, then increased again to the third maximum value on days 13–14.

The probe for T-15 binding cells—the radioiodinated TEPC-15 myeloma protein—could bind in at least three ways: by the Fc fragment, by the PC-specific binding site and by the T-15 idiotype. Thus, the relative changes in T-15 binding on splenocytes following Pn immunisation could result from members of Fc receptor-bearing cells or from residual antigen. The MOPC-315 and the McPC-603 myeloma proteins acted as controls for these variables; in particular, the McPC-603 protein has the PC binding paratope and IgA isotype but lacks the T-15 idiotype<sup>14</sup>. The binding of the control probes, MOPC-315 and McPC-603, remained relatively constant ( $\pm 5\%$  of the day 0 value) over the 14-d period following immunisation with Pn. The biphasic pattern of T-15 binding was retained even when cells were incubated with  $^{125}$ I-TEPC-15 in a large excess of McPC-603 protein (Table 1). Thus, it is likely that the T-15 probe predominantly measured anti-idiotypic cells.

Our data on PFC oscillation agree with previous results showing a cyclical pattern of *Escherichia coli* lipopolysaccharide-specific PFC in mice<sup>15</sup> and PFC against human immunoglobulin in rabbits<sup>16</sup>. In the latter study, PFC peaks were observed on days 6 and 12 after immunisation and, as in our experiments, this oscillation was not reflected in the serum antibody levels.

Earlier work from Nisonoff's laboratory has demonstrated the sequential activation of antigen-reactive clones during the immune response<sup>17</sup>. To ensure that the T-15 idiotype dominated both anti-Pn PFC peaks, we carried out a plaque-inhibition assay using a rabbit anti-T-15 antiserum (rendered specific by absorptions with: (1) pooled murine IgM; (2) MOPC-315; and (3) C57BL/6 spleen cells). The addition of this serum at a dilution of 1:500 inhibited both the day 6 and day 12 BALB/c anti-Pn PFC response by  $\geq 80\%$ . The C57BL/6 anti-Pn response was inhibited by  $\leq 9\%$  and the BALB/c anti-TNP response was unaffected.

The increase of T-15 binding by splenic lymphocytes (day 3) suggests an expansion of the anti-idiotypic clones, presumably through cell proliferation. Nonetheless, alternative explanations for the increased binding, such as shedding and passive uptake of T-15 receptors or a trapping of circulating, receptor-bearing lymphocytes in the spleen, cannot be excluded *a priori*. The expansion of the anti-idiotypic clones seems to be cyclical. However, the decrease in T-15 binding observed between the peaks may be partly due to occupation of the receptors by anti-Pn antibody. Because the serum anti-Pn titres do not oscillate, it is more likely that this would result from antibody production *in situ*. Within the micro-environment of the spleen, local concentrations of idiotype antibody might be sufficient to occupy a significant number of receptors on idiotype-binding cells. That the second peak of T-15 binding (day 10) does reflect an expansion of the anti-idiotypic clone rather than a mere unmasking of the receptors for the idiotype is supported by Cosenza's finding of anti-T-15 PFC during the immune response to Pn<sup>18</sup>. These PFC appeared on days 7–8 after immunisation,

following the decline of anti-Pn PFC. We find that at this time the T-15 binding begins to increase and continues to do so until days 10–11; presumably, the binding assay detects cells other than PFC.

Our data demonstrate the periodic expansion of an antigen-activated idiotype clone associated with a reciprocal expansion and diminution of cell-associated, anti-idiotypic (idiotype binding) activity. The pattern is consistent with the hypothesis of a regulatory network based on an idiotype-anti-idiotypic equilibrium. It is tempting to speculate that the out-of-phase expansions of antibody-forming cells and cell-associated anti-idiotypic activity result from the interaction of the idiotype clone with its anti-idiotypic regulators.

We thank Dr J. Novotny for discussions and Ms C. Berman for technical assistance and acknowledge the gift of strain R36a *S. pneumoniae* by Dr H. Kohler. G.K. is the recipient of a Rockefeller Foundation Fellowship. The research was supported in part by American Cancer Society grant IM-35 and by USPHS grant CA 14922 from the NCI.

## A possible mechanism for insulin resistance and hyperglycaemia in NZO mice

THE New Zealand obese (NZO) mouse is characterised by obesity, hyperinsulinaemia, insulin resistance and mild glucose intolerance<sup>1–8</sup>. It has been thought of as a model of the adult-type human diabetes mellitus, but neither the genetics of the NZO syndrome nor its basic cause have been elucidated. The metabolic disturbances found in these mice, for example

**Table 1** Effect of NZO serum on insulin binding to normal mouse liver membranes

	Control serum	NZO serum				
		1:2	1:4	1:8	1:16	1:32
<sup>125</sup> I-insulin specifically bound (% of total)	21.5	23.9	8.5	11.6	13.1	17.0

Approximately 100 µg of mouse liver membrane (10-week-old NIH white mice) was exposed to 50-µl dilutions of NZO serum in pooled control serum for 1 h at 24 °C. The membranes were then pelleted in a Beckman Microfuge and washed twice by resuspension in 0.1 M sodium phosphate buffer at 4 °C. <sup>125</sup>I-insulin (50 pg; ~13,000 c.p.m.) in 100 µl of 0.1% bovine albumin-0.1 M sodium phosphate buffer, pH 7.4, was added to the washed membranes, with or without excess unlabelled insulin (10 µg) and the mixtures incubated for 90 min at 15 °C. Membranes were pelleted, washed and counted for <sup>125</sup>I-insulin radioactivity in a gamma counter. Radioactivity bound in the presence of excess unlabelled insulin (nonspecific binding) was subtracted to give specific binding. Results are the means of two experiments each performed in triplicate.

increased rates of lipogenesis<sup>9-12</sup> and defects in insulin secretion<sup>8,13,14</sup>, could well be secondary to chronic hyperinsulinaemia and hyperglycaemia. Because the NZO strain appeared to share a common ancestry with the NZB model of systemic autoimmune disease<sup>1,2,15</sup> we felt that the metabolic syndrome in the NZO mouse might have an immune basis. It was originally suggested that the insulin resistance of NZO mice might be due to an antagonist to the action of insulin<sup>2</sup>. We now report that NZO serum contains a globulin, probably an autoantibody, which inhibits insulin binding and indirectly immunoprecipitates the solubilised insulin receptor.

Initial studies were performed with pooled NZO sera from mice of both sexes older than 12 months. We then developed our own inbred colony from mice derived from the original stock of Bielschowsky and Bielschowsky<sup>1</sup>. The mice had free access to food and water and became obviously obese by 8-10 weeks of age. Orbital sinus blood samples were obtained between 9 and 10 a.m. from 5-20-week-old animals in the post-absorptive state.

The effect of NZO serum on insulin binding was studied by preincubating a source of insulin receptors (NZO, BALB/c or NIH mouse liver membranes, human placental membranes, or cultured IM-9 lymphocytes) with NZO serum serially diluted in control mouse serum (NZW, BALB/c, NIH or CBA mice), followed by washing and measurement of specific <sup>125</sup>I-insulin binding. The preparation of receptors<sup>16,17</sup>, and biologically active <sup>125</sup>I-insulin<sup>18</sup>, and the binding technique<sup>19</sup>, have been described previously. Preincubation of normal mouse liver

**Table 2** Insulin binding to normal mouse liver membranes preincubated with serum from two NZO mice, before and after treatment of each serum with anti-mouse κ antiserum

	<sup>125</sup> I-insulin specifically bound (% of total)	
	Untreated	Treated
Control serum	12.3	12.1
NZO-3	2.5	6.0
NZO-4	5.9	10.3

Serum (75 µl) from male NZO mouse no. 3, female NZO mouse no. 4 and a normal NIH mouse pool was incubated with 75 µl of rabbit anti-mouse κ antiserum (Miles, 64-366 lot 11) or with 75 µl of non-immune rabbit serum for 18 h at 4 °C. Immune complexes in the samples treated with anti-κ serum formed visible precipitates after centrifugation in a Beckman Microfuge. The supernatants were aspirated, diluted a further 1:2 in normal mouse serum (final dilution 1:4) and then tested for an inhibitory effect on <sup>125</sup>I-insulin binding, according to the protocol described in Table 1. Results are the means of two experiments each performed in triplicate.

membranes with dilutions of NZO serum resulted in inhibition of subsequent <sup>125</sup>I-insulin binding (Table 1). For unknown reasons, undiluted serum either had no effect or actually increased binding slightly. Inhibition was specific for <sup>125</sup>I-insulin and was not seen for <sup>125</sup>I-growth hormone. However, preliminary experiments have shown a smaller effect of NZO serum on binding to NZO membranes, which may be due to antigenic modulation by previous exposure to antibody as the affinity of the receptor in NZO membranes is impaired (data not shown). Maximum inhibition of binding was 20-80% of control and was seen at dilutions between 1:4 and 1:32. Inhibition was never observed at serum dilutions greater than 1:64. Re-exposure of membranes to fresh serum did not cause a further decrease in binding (data not shown). Similar results were obtained in heterologous systems using either human placental membranes or cultured human IM-9 lymphocytes as receptor sources. Treatment of NZO sera with anti-mouse κ antiserum partially removed the inhibitory activity (Table 2), suggesting that the inhibitory factor was an immunoglobulin.

An immunoprecipitation assay for receptor antibodies was performed by incubating serum with Triton-solubilised mouse liver or human placental membranes pre-labelled with <sup>125</sup>I-insulin, followed by addition of a second (precipitating) antibody<sup>20,21</sup>. Solubilised mouse liver receptors were immunoprecipitated by NZO serum in a dose-dependent manner, after addition of anti-mouse globulin antiserum (Table 3). Precipitation of <sup>125</sup>I-insulin radioactivity in excess of control was not observed with NZO sera in the absence of receptor, thereby excluding the possibility of antibodies to insulin itself.

**Table 3** Immunoprecipitation of <sup>125</sup>I-insulin-labelled receptors by NZO serum and anti-mouse globulin antiserum

	Control serum	NZO serum			
		1:10 <sup>3</sup>	1:10 <sup>2</sup>	1:20	1:10
c.p.m. (% of total)	1.2	1.2	1.7	3.5	5.9

Normal mouse liver membranes (~50 mg ml<sup>-1</sup>) were solubilised by mixing them with 1% Triton (v/v)-0.1 M sodium phosphate buffer, pH 7.4, for 1 h at 24 °C. The mixture was then centrifuged at 200,000g for 1 h. 20 µl (~80 µg of protein) of the clear supernatant containing solubilised insulin receptors was incubated for 1 h at 24 °C with a trace amount of <sup>125</sup>I-insulin (50 pg; ~13,000 c.p.m.) in a total volume of 180 µl of 0.1 M sodium phosphate buffer. Pooled NZO serum (20 µl) serially diluted in control NZW serum, or control serum alone, was then added and incubations continued for a further hour at 24 °C. The mixtures were cooled to 4 °C and 50 µl of rabbit anti-mouse globulins (Behring Diagnostics lot A2929C) was added for a further 4 h at 4 °C. Immune complexes, which formed a visible suspension, were precipitated by centrifugation in a Beckman microfuge, washed once with 0.1% Triton buffer and counted in a gamma counter. When the receptor was omitted from the initial Triton buffer-<sup>125</sup>I-insulin mixture, radioactivity subsequently present in the immune precipitate was equivalent to that in the control, thus excluding the presence of antibodies to <sup>125</sup>I-insulin itself. Results are the means of two experiments each performed in triplicate.

Immunoprecipitation was more sensitive than the binding inhibition assay, activity being detected up to serum dilutions of 1:100 with titres (serum dilutions causing half-maximum immunoprecipitation) ranging from 1:10 to 1:40. We attempted to determine the class of antibody involved by using a variety of second antisera to mouse immunoglobulins A, G and M. Antiserum to mouse IgA was ineffective. Weak immunoprecipitation was obtained in the majority of sera tested by using either anti-mouse 7S globulins or anti-mouse IgM. We are investigating the possibility that the receptor antibody in NZO sera may not be well recognised by commercially available antisera, or may be a low molecular weight IgM.

A number of lines of evidence favour an immune basis for the metabolic abnormalities in NZO mice. First, the mice are distantly related to the autoimmune NZB strain<sup>1,2,15</sup>. Second, the Bielschowskys<sup>2</sup> demonstrated improvement of obesity, hyper-

glycaemia and insulin resistance during pregnancy and after treatment with stilboestrol. Although pregnancy is a state of 'physiological' insulin resistance it is also a state of 'immunological inertia'<sup>22</sup>, which might explain its beneficial effect in an autoimmune disease. Remission after stilboestrol therapy may have been due to the immunosuppressive effect of the steroid, particularly as gonadectomy was without effect in either sex<sup>2</sup>. Finally, the finding in NZO mice of a relatively high incidence of spontaneous and carcinogen-induced tumours<sup>23</sup> would be consistent with an underlying immune disorder.

The relationship of the antibody to age, sex and metabolic status is now being studied to define the pathological role of the antibody and to determine whether the NZO model is the counterpart of the recently described human syndrome of insulin-resistant diabetes associated with antibodies to the insulin receptor<sup>19,21</sup>.

We thank Dr Richard Larkins for NZO mice sera, Dr Lieselotte Herberg for mice derived from the Bielschowsky stock, Dr Jesse Roth for support and advice and Mrs Beverly Knight for secretarial assistance. This work was initiated while L.C.H. was a recipient of a C. J. Martin Fellowship from the National Health and Medical Research Council of Australia. A.I. was supported by a grant from the Juvenile Diabetes Foundation.

## FSH induction of functional LH receptors in granulosa cells cultured in a chemically defined medium

THE rat ovarian granulosa cell is an excellent model for studying the mechanisms and control of hormone-dependent cell differentiation. During graafian follicle development, the granulosa cells sequentially develop specific membrane receptor sites for follicle-stimulating hormone (FSH)<sup>1,2</sup> and luteinising hormone (LH)<sup>3</sup>. *In vivo* studies on the mechanism of granulosa cell differentiation have established that FSH induces the

**Fig. 1** FSH induction of hCG binding sites in rat granulosa cells cultured in a chemically defined medium. ●, Without FSH (in the presence or absence of serum); ○, with FSH and 10% hypophysectomized female rat serum; ■, with FSH in the absence of serum. Immature female rats (Sprague-Dawley, 23–25 d old) were hypophysectomized and implanted with a 10-mm silastic capsule containing diethylstilboestrol (DES) to stimulate granulosa cell proliferation. Five days after hypophysectomy, the ovaries were removed and the granulosa cells collected and cultured as previously described<sup>9</sup>. The culture medium consisted of McCoy's 5a medium (modified; GIBCO) supplemented with 2 mM L-glutamine, 100 U ml<sup>-1</sup> penicillin and 100 µg ml<sup>-1</sup> streptomycin sulphate. The following agents were added where indicated; purified oFSH (Papkoff G4-150C; FSH potency = 50 × NIH-FSH-SI U per mg; LH potency < 0.01 NIH-LH-SI U per mg); androstenedione (10<sup>-7</sup> M; substrate for aromatization) and 10% animal serum from immature hypophysectomized female rats. The granulosa cells were cultured for 2 days in a 95% air–5% CO<sub>2</sub> incubator (37 °C). After the incubation, the granulosa cells were scraped from the dish with a rubber policeman, washed twice with 5-ml portions of Dulbecco's phosphate buffer with 0.1% bovine serum albumin (BSA) and the final pellet resuspended in the same buffer. Cell number was determined using a haemocytometer. Highly purified hCG (CR-119; 11,600 IU per mg) was iodinated by the procedure of Greenwood *et al.*<sup>10</sup>. The specific activity (80,000–130,000 c.p.m. per ng) and maximal binding capacity (40–45%), were determined by radioligand receptor assay using rat testicular membranes<sup>11</sup>. Samples (50 µl) of granulosa cells (1 × 10<sup>6</sup> cells) were incubated for 16 h (23 °C) with 100 µl of [<sup>125</sup>I]-hCG (~1 × 10<sup>-10</sup> M) with and without unlabelled hCG (100 IU Pregnyl)<sup>12</sup>. The absence of androstenedione from media did not modify the FSH effect, indicating that FSH alone induced the LH/hCG receptors. Data points indicate mean ± s.e. of six separate experiments with five dishes per determination per experiment.

appearance of the LH receptor sites in the granulosa cell<sup>4,5</sup>. The FSH-induced increase in LH receptors is essential for preparing the graafian follicle for the pre-ovulatory surge of LH which initiates ovulation and subsequent luteinisation of the granulosa cells. Studies of cultured granulosa cells have led to the suggestion that the FSH induction of LH receptors is not a direct process but requires an interaction between the granulosa cell and other ovarian cell types, a concept consistent with the known importance of cell–cell interaction in cell differentiation<sup>6</sup>. This hypothesis stemmed from the observation that LH receptors can be induced by FSH in granulosa cells *in vivo* and in organ cultures of intact ovarian follicles, but not in isolated granulosa cells cultured as monolayers in medium containing serum<sup>7,8</sup>. We show here that the inability of previous workers<sup>7,8</sup> to induce LH receptors in isolated granulosa cells may have been due to the use of serum in their tissue culture medium. We demonstrate that specific, high-affinity LH/hCG receptors can be induced by FSH in isolated granulosa cells cultured in a chemically defined medium, but not in isolated granulosa cells cultured with serum. In addition, we show that these receptors are capable of mediating important steroidogenic responses.

As shown in Fig. 1, the hCG-binding capacity of freshly collected granulosa cells was very low ( $0.32 \pm 0.014$  fmol per  $10^6$  cells;  $192 \pm 8$  sites per cell; mean  $\pm$  s.e. of six separate experiments). Culturing granulosa cells for 2 days in medium containing purified ovine FSH and 10% serum from hypophysectomised female rats (or serum from horse, pig or fetal calf), did not increase the  $^{125}$ I-hCG-binding capacity as compared with untreated control cultures or freshly isolated granulosa cells (Fig. 1). In contrast, culturing granulosa cells in serum-free medium containing FSH resulted in a dramatic increase in  $^{125}$ I-hCG binding as compared with control cells (Fig. 1). A small increase in binding was observed at day 1, after which the binding capacity increased 10-fold, to reach  $3.61 \pm 0.60$  fmol per  $10^6$  granulosa cells ( $2,095 \pm 325$  sites per cell) by day 2.

Figure 2a shows that the hCG receptors induced by FSH are hormone specific. Increasing concentrations of unlabelled hCG, but not prolactin, competed with  $^{125}$ I-hCG for binding sites in a dose-dependent manner. Moreover, unlabelled FSH inhibited binding only at doses 1,000 times higher than those of hCG, an inhibition that can be explained by contamination of the FSH preparation with LH. Scatchard analysis of the binding data (Fig. 2b) suggested the presence of two classes of  $^{125}$ I-hCG-binding sites. This is consistent with our previous studies using granulosa cells from adult rats<sup>12</sup>. The calculated  $K_d$  ( $1.4 \times 10^{-11}$  M) of the high-affinity binding site (Fig. 2b) is of the same order as that determined in previous studies with rat granulosa cells<sup>3,12</sup>. Furthermore, FSH treatment for 2 days *in vivo* increased  $^{125}$ I-hCG binding in the granulosa cell to a level comparable with that found in the present *in vitro* study (unpublished result).

To determine if the LH/hCG receptors induced by FSH were functionally active, we investigated the effects of purified LH and FSH on the biosynthesis of progesterone and oestrogen (Table 1). In this experiment, the granulosa cells were cultured for 2 days in a chemically defined medium with and without LH or FSH, washed, and then recultured for another 2 days in the presence and absence of the purified gonadotropins. During the 0–2 and 2–4 day culture period, FSH caused a marked stimulation of oestrogen and progesterone production, whereas LH had little effect, indicating that the granulosa cells are responsive to FSH, but not to LH. However, after 2 days of FSH priming LH caused a highly significant ( $P > 0.001$ ) increase in both oestrogen and progesterone production compared with the control (FSH; control) cultures. This result shows that the LH/hCG receptors induced by FSH are functionally active. The present finding that purified LH stimulates oestrogen formation is important as it demonstrates for the first time that LH, like FSH, can stimulate aromatase enzyme activity in the granulosa cell.

**Table 1** Induction by FSH of the ability of purified LH to stimulate progesterone and oestrogen production by isolated rat granulosa cells *in vitro*

Treatment 0–2 d; 2–4 d	Progesterone (ng ml <sup>-1</sup> )		Oestrogen (ng ml <sup>-1</sup> )	
	Day 0–2	Day 2–4	Day 0–2	Day 2–4
Control; Control	$0.10 \pm 0.01^*$	$0.22 \pm 0.01$	$< 0.04$	$< 0.04$
LH; LH	$0.50 \pm 0.01$	$0.27 \pm 0.01$	$0.19 \pm 0.01$	$0.07 \pm 0.01$
FSH; FSH	$21.67 \pm 1.92$	$8.35 \pm 0.71$	$4.28 \pm 0.22$	$4.09 \pm 0.22$
FSH; LH	—†	$7.32 \pm 0.47^\ddagger$	—	$2.49 \pm 0.14^\ddagger$
FSH; Control	—	$1.73 \pm 0.13$	—	$1.11 \pm 0.10$

Granulosa cells ( $1 \times 10^5$  viable cells) were cultured for 4 days in McCoy's 5a medium with  $10^{-7}$  M androstenedione, either alone or with purified Papkoff ovine FSH ( $100$  ng ml<sup>-1</sup>) or purified oLH ( $100$  ng ml<sup>-1</sup>; Papkoff; G3-222B; LH potency =  $2.75$  NIH-LH-SI U per mg; FSH potency =  $0.001$  NIH-FSH-SI U per mg). After 2 days the media were collected, and the granulosa cells were washed twice with 2-ml portions of McCoy's 5a medium. The cells were then recultured for 2 days in 1 ml of fresh medium containing  $10^{-7}$  M androstenedione and hormones where indicated. Progesterone and oestrogen in the media were measured by radioimmunoassay<sup>13</sup>.

\* Mean  $\pm$  s.e.;  $n = 8$ .

† Same values designated in the FSH (day 0–2).

‡ Significantly different from control group (FSH; control) ( $P < 0.001$ ) as determined by analysis of variance.

The present results demonstrate that purified FSH can induce the appearance of specific, high-affinity LH/hCG receptors in isolated granulosa cells and that the LH/hCG receptors are capable of mediating two important biological responses, namely, oestrogen and progesterone biosynthesis. This direct action of FSH in the granulosa cell can explain the increased responsiveness of the developing pre-ovulatory follicle to LH during the follicular phase of the reproductive cycle. The fact that the characteristics of the LH/hCG receptors ( $K_d$  and number of binding sites) induced in the granulosa cell by FSH *in vitro* are similar to those induced by FSH *in vivo*, suggested that the present *in vitro* observations reflect a normal physiological event. Our finding that FSH induces the appearance of LH/hCG receptors in isolated granulosa cells cultured in a chemically defined medium (without serum) strongly suggests that this basic action of FSH does not require the participation of other ovarian cells, as recently proposed by Nimrod *et al.*<sup>7</sup>.

**Fig. 2** Specificity and binding characteristics of LH/hCG receptors induced by FSH *in vitro*. *a*, Specificity of  $^{125}$ I-hCG binding to granulosa cells after 2 days of culture with oFSH ( $100$  ng ml<sup>-1</sup>) in chemically defined medium (without serum). Granulosa cells ( $1 \times 10^6$  cells) (prepared as described in legend to Fig. 1) were incubated in  $300$   $\mu$ l (phosphate buffered saline– $0.1\%$  BSA) buffer for  $16$  h ( $23^\circ\text{C}$ ) with  $20,000$  c.p.m. of  $^{125}$ I-hCG and the indicated amounts of unlabelled hCG (CR-119), purified human FSH (NIH-FSH-HSI) or ovine prolactin (NIH-P-SI2). Data points represent the mean of four determinations. *b*, Scatchard analysis of binding data from displacement curve shown in *a*.  $K_d$ , Dissociation constant =  $1.4 \times 10^{-11}$  M; number of binding sites =  $3,157$  sites per cell.

Our failure to induce LH/hCG receptors with FSH in granulosa cells cultured in medium containing serum is consistent with previously published data<sup>7,8,14</sup>. Moreover, our results are consistent with those of an earlier study<sup>14</sup> which reported an FSH stimulation of LH binding in cultured porcine granulosa cells, although the data from these cells were variable and complicated by the loss of pre-existing LH receptors during the incubation. The nature of the inhibitory effect of serum is unknown; however, it may result from the presence of factors in serum which have been reported to inhibit FSH binding to receptors<sup>15</sup>.

Experiments with animal cells in culture have usually used serum because the maintenance and growth of functionally differentiated cell cultures require certain factors found in serum<sup>16</sup>. However, the addition of serum to culture media has made it difficult, sometimes impossible, to interpret the action of specific regulatory substances. We conclude that the *in vitro* culture system described here offers an important model for investigating and defining the control mechanisms of hormone-dependent differentiation of a normal mammalian cell in a chemically defined medium.

## Glucocorticoids inhibit expression of Fc receptors on the human granulocytic cell line HL-60

GLUCOCORTICOIDS decrease levels of circulating peripheral lymphocytes and immunoglobulins, inhibit mitogen- and antigen-induced blastogenesis of cultured lymphocytes and decrease bactericidal activity of granulocytes and other phagocytic cells<sup>1-4</sup>. Fc receptors on granulocytes are thought to play a vital part in adherence of antibody-coated particles to the surfaces of these cells, a step which initiates phagocytosis<sup>5</sup>. Factors which regulate the expression of the Fc receptor could therefore influence phagocytic capability, and it has been suggested that glucocorticoids might act in such a way<sup>6,7</sup>. We report here that glucocorticoids inhibit expression of the Fc receptor on the human promyelocytic cell line HL-60 (ref. 8). This inhibition is not accompanied by increased cell death, reduced proliferation or a general reduction in protein synthesis.

For assay of Fc receptors, IgG1 was purified from the serum of a patient with multiple myeloma. The precipitate obtained by 45% saturation with ammonium sulphate was dissolved in acetic acid-ethylene diamine buffer (0.1M, pH 7.0) and desalted by passing through a column (1×20 cm) of Biogel P-100 (Bio-Rad). The excluded peak from the column was placed on a column (1×15 cm) of Sephadex QAE-50 (Pharmacia) and eluted with acetic acid-ethylene diamine buffer. The IgG1 obtained was pure by immunoelectrophoresis, and contained only traces of other proteins by gradient gel and cellulose acetate electrophoresis. The protein was iodinated with <sup>125</sup>I (Amersham, 11-17 Ci μg<sup>-1</sup>) by the solid phase lactoperoxidase method<sup>9,10</sup>. Protein concentration was determined by absorbance at 280 nm ( $A_{280}^{1\%} = 11.4$ ). Specific activities were between 20 and 57 Ci mmol<sup>-1</sup>.

This labelled IgG1 was used to determine the number and affinity of Fc binding sites by the modification of the competitive binding assay of Unkeless and Eisen<sup>11</sup> described in the legends to Figs 1 and 2. The assay showed high specificity for the Fc fragment of IgG1. In competition experiments with 0.5-5 nM

**Fig. 1** Time course with HL-60 cells of the effect of 200 nM dexamethasone on Fc receptor sites per cell (●), leucine incorporation (□) and viable cell counts (○). HL-60 cells\* were cultured in RPMI 1640 (GIBCO) with 10% fetal calf serum, penicillin (50 units ml<sup>-1</sup>) and gentamycin (50 μg ml<sup>-1</sup>) at 37°C in humidified room air containing 5% CO<sub>2</sub>. Dexamethasone dissolved in medium at 0.1 mM was added at time zero to three flasks containing 50 ml cell suspension (2×10<sup>5</sup> cells per ml). An equivalent amount of medium was added to three control flasks. At 15 min and 24, 48 and 72 h, 4×10<sup>6</sup> cells were removed and washed twice with 15 ml Dulbecco's phosphate-buffered saline (GIBCO) containing 1 mg ml<sup>-1</sup> bovine serum albumin (2×recrystallised, Calbiochem) (PBS-BSA) at room temperature. The cells were incubated for 30 min in 15 ml PBS-BSA (2-8×10<sup>5</sup> cells per ml) at 37°C with 60 c.p.m. shaking to dissociate endogenous immunoglobulins in fetal calf serum from the Fc receptors. They were then resuspended in PBS-BSA at 5×10<sup>7</sup> cells per ml, and 20 μl aliquots were incubated in duplicate with 20 μl of <sup>125</sup>I-labelled IgG1 (40 nM), with and without unlabelled IgG1 (1 μM) in albuminised 1.5-ml conical polypropylene Eppendorf centrifuge tubes (Brinkman) for 30 min at 37°C with 60 c.p.m. shaking. At the end of the incubation the cell suspension was pipetted over 350 μl fetal calf serum at 0°C in 400-μl microfuge tubes (Brinkman) and centrifuged for 30 s at 10,000g. The supernatant was rapidly aspirated and the tips of the tubes containing the cell pellet counted in a gamma counter at an efficiency of 70% for <sup>125</sup>I. The difference between the c.p.m. bound in the presence (an almost negligible amount, as shown in Fig. 2) and absence of 1 μM competing unlabelled IgG1 (that is, the c.p.m. corresponding to saturably bound IgG1) was calculated as molecules per cell. Since at 40 nM IgG1 nearly saturates the Fc receptor sites (see Fig. 2) this value gives a close estimate of the total number of Fc receptor sites per cell. Leucine incorporation was measured by removing 100-μl aliquots from each of the flasks and incubating for 4 h at 37°C under 5% CO<sub>2</sub> in humidified room air in microtitre plates (Costar) with 100 μl of a solution (3 μCi ml<sup>-1</sup>) of <sup>3</sup>H-leucine (NEN, 297 Ci mol<sup>-1</sup>) in GIBCO minimum essential medium. Cells were collected on glass fibre filters using a multiple automated sample harvester, and after drying were counted in a toluene-based scintillation fluid at an efficiency of 50% for <sup>3</sup>H. Viable cell counts were determined as the product of the fraction viable by Trypan blue exclusion and the cell count determined with a Coulter counter. Viabilities of control and dexamethasone-treated cells were not significantly different, and always remained above 95%. Each point represents the mean for determinations on three control flasks and three flasks with dexamethasone. For the controls, the number of Fc receptor sites remained essentially constant at about 16,000 sites per cell over the whole time period; the rates of leucine incorporation increased slightly, and the viable cell counts increased from 200 to 650 cells per μl.

<sup>125</sup>I-labelled IgG1 the Fc fragment, prepared by papain hydrolysis and affinity chromatography, at 10 nM reduced binding of labelled IgG1 by 50% and at 100 nM by 90%, as effectively as unlabelled IgG1. The Fab fragment, similarly prepared, did not compete at all. Human IgG3 competed as well as IgG1, whereas IgG2 and IgG4 competed weakly and IgA did not compete. Protein A (Pharmacia) at 100 nM reduced binding by 50%. It failed to reduce binding further at concentrations as high as 50 μM, suggesting among other possibilities that there may be more than one class of Fc receptor on HL-60 cells.

Figure 1 illustrates the time course of effects of 200 nM dexamethasone on HL-60 cells. Within 24 h there was a significant decrease in the number of Fc receptor sites, which by 48-72 h had fallen to ~65% of the controls without steroid. In other experiments the levels reached varied from 75 to 40%. They remained low for at least 8 d in the continued presence of dexamethasone, but returned to normal within 48 h of removal of the steroid. Over the 72-h period there was no decrease in overall leucine incorporation, so there was no general reduction of protein synthesis. Similarly, cell proliferation was not decreased.

The reduction in the number of Fc receptor sites was not associated with a change in the affinity of the receptor for IgG1. Control cells and cells treated with 1  $\mu$ M dexamethasone for 72 h bound IgG1 with the same dissociation constant of 10 nM (Fig. 2).

Prednisolone and cortisol at 1  $\mu$ M after 48 h reduced Fc receptor sites from 14,400 to about 8,000 per cell. Oestradiol and progesterone at 1  $\mu$ M had no effect. Dexamethasone gave a half-maximal response at 10 nM, comparable to effects of dexamethasone on other cellular processes<sup>12</sup>. This concentration is consistent with a process mediated by binding to glucocorticoid receptors in these cells, since it corresponds with the dissociation constant we have determined separately for binding of dexamethasone to glucocorticoid receptors in HL-60 cells at 37 °C. These cells contain numbers of glucocorticoid receptor sites similar to myeloblasts from patients with acute myelogenous leukaemia<sup>13</sup>. After Fc receptors are reduced to about 50% by treatment with trypsin, their reappearance is almost completely blocked by glucocorticoids. In the absence of steroid they return to normal after 48 h.

In two previous studies<sup>4,14</sup>, effects of glucocorticoids on Fc receptors in human monocytes were investigated. The only effect detected, a decrease in IgG binding, required steroid concentrations of 0.1–1 mM, far above pharmacological concentrations, and the effect was not specific for glucocorticoids<sup>14</sup>. The duration of exposure to steroids, 90–120 min, was much less than we find necessary to produce significant effects. Furthermore, the immune adherence techniques used would probably not detect effects of the kind we describe. Methods involving rosette formation with antibody-coated red cells or binding of fluorescence-labelled immune complexes can detect cells with more than some undetermined threshold level of Fc receptors (probably 10,000–20,000 sites per cell), but do not permit accurate quantitation of binding.

Our finding that glucocorticoids reduce the number of Fc receptors on HL-60 cells is important in at least two ways. First, it establishes in a pure cell line an effect that is manifested on a discrete membrane structure and that, in contrast to what is often observed<sup>12</sup>, is not accompanied by general inhibition of protein synthesis. Second, it may provide a molecular explanation for the suppressive effects of glucocorticoids on the phagocytosis and destruction of autologous tissue that characterise

some immune responses mediated by Fc receptors. The observation<sup>16,17</sup> that patients with diseases such as autoimmune haemolytic anaemia and autoimmune thrombocytopenia frequently show clear improvement and decreased phagocytic activity in their granulocytes after treatment for 24–48 h with glucocorticoids could well be explained by a decrease in the number of Fc receptors. The time course is too rapid to be accounted for by known effects on human immunoglobulin levels<sup>2</sup> but is similar to that needed for the reduction in Fc receptors that we describe here. The assay for Fc receptors may also prove useful for studying other factors which regulate this immunologically important structure.

We thank Drs Robert Gallo, Robert Gallagher and Steven Collins for providing HL-60 cells. These studies were supported in part by grants CA 17323, AM 03535 and CA 17643 from the NIH and by the Core Grant (CA 23108) of the Norris Cotton Cancer Center.

**Fig. 2** Scatchard plot of binding of IgG1 to Fc receptors of HL-60 cells after incubation with 1  $\mu$ M dexamethasone.  $\nabla$ , Controls without dexamethasone.  $\Delta$ , Cells incubated with 1  $\mu$ M dexamethasone. Cells were incubated with or without dexamethasone for 96 h and washed in PBS-BSA as described for Fig. 1. They were then resuspended at  $1.6 \times 10^8$  cells per ml in PBS-BSA. Aliquots were incubated as described for Fig. 1 with  $^{125}$ I-labelled IgG1 at 12 concentrations from 100 pM to 1  $\mu$ M. After the incubation the tubes were centrifuged at 10,000g for 10 s and 20  $\mu$ l supernatant removed and counted to determine the final concentration of free labelled IgG1. The tubes were then cooled to 3°C, 1.2 ml of PBS-BSA at 0 °C was added and the cells were resuspended. After 5 min the tubes were centrifuged at 12,000g for 4 min, the supernatant aspirated and the tips counted as described for Fig. 1 to determine bound  $^{125}$ I-labelled IgG1. The data are plotted by the method of Scatchard<sup>15</sup>. Nonsaturably bound IgG1 was not subtracted for these results. Bound IgG and free IgG on the ordinate are given in units of c.p.m. per 20  $\mu$ l of cell suspension; the values on the ordinate therefore represent the bound IgG1 as a fraction of the free IgG1 at equilibrium.

## Negative and positive inotropic action of vanadate on atrial and ventricular myocardium

VANADATE (vanadium in the +5 oxidation state) occurs widely in animal tissues<sup>1</sup>, and has been suggested to be the first regulatory agent of  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ ; it inhibits ATPase preparations from kidney and red blood cells at very low concentrations<sup>2–4</sup>. Hackbarth *et al.* have shown that vanadate produces positive inotropic effects in isolated cat papillary muscles<sup>5</sup>, raising the question of whether this positive inotropic effect is accompanied by an inhibition of myocardial  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ , and, if so, whether both effects occur at similar concentrations of vanadate. We report here that we have observed a striking difference in the inotropic actions of vanadate on isolated heart preparations. Although the force of contraction was reduced in atria, it was increased in ventricular myocardium. This dissociation correlated well with changes in transmembrane potential but not with inhibition of  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$  isolated from both atrial and ventricular myocardium.

Left and right atria and papillary muscles from guinea pig and cat, and atrial and ventricular trabeculae of the cow, were mounted in glass chambers for measuring isometric contraction. The bathing solution (20 ml), containing (mmol l<sup>-1</sup>) NaCl 118, KCl 4.7, CaCl<sub>2</sub> 2.5, MgSO<sub>4</sub> 1.6, NaHCO<sub>3</sub> 24.9, NaH<sub>2</sub>PO<sub>4</sub> 1.2

**Fig. 1** Change in the force of contraction in papillary muscle (*a*) and atria (*b*).  $ED_{50}$  values ( $\mu\text{mol l}^{-1} \pm \text{s.e.m.}$ ) were calculated by fitting the logit function to the experimental data using the least-square method: papillary muscle, guinea pig ( $\square$ )  $110.3 \pm 1.9$ , cat ( $*$ )  $124.1 \pm 2.6$ ; left atria, guinea pig ( $\circ$ )  $4.73 \pm 0.10$ , cat ( $\triangle$ )  $28.1 \pm 0.47$ ; right atria, guinea pig ( $\bullet$ )  $3.29 \pm 0.06$ , cat ( $\blacktriangle$ )  $14.8 \pm 0.28$ . The curves were plotted according to the equation

$$y(x) = \frac{100}{1 + 10^{-s(x - \log ED_{50})}}$$

where  $s$  = slope and  $x$  = log concentration<sup>6</sup>.

and glucose 11.1, was equilibrated with 95%  $\text{O}_2$  and 5%  $\text{CO}_2$  (pH 7.4) at 31 °C. Increasing doses of  $\text{Na}_3\text{VO}_4$  (Fluka) were added to the bathing solution cumulatively every 15 min. The preparations were driven electrically by platinum electrode stimulation at 1 Hz (guinea pig) or 0.5 Hz (cat, cow). Pulse duration was 1 ms (intensity 20% above threshold, preload of atria  $10^{-2}$  N, that of papillary muscles and trabeculae  $7 \times 10^{-3}$  N  $\text{mm}^{-2}$ ). Action potentials of the isometrically contracting atrial and ventricular tissues were recorded with glass micro-electrodes filled with 3 mol  $\text{l}^{-1}$  KCl (resistance 10–30 M $\Omega$ ) using a horizontal Perspex chamber, perfused with increasing concentrations of  $\text{Na}_3\text{VO}_4$ .

Figure 1 shows the inotropic action of vanadate. In a concentration range of 25–500  $\mu\text{mol l}^{-1}$ , vanadate increased the force of contraction of papillary muscles. In contrast, it strongly decreased the force of contraction of stimulated left atria and spontaneously beating right atria. The effect appeared immediately on perfusion and steady-state conditions were reached within 10 min. On washing with drug-free bathing solution, the force of contraction of the atria increased above control levels and regained initial values after about 15 min. At high concentrations of vanadate ( $>1$  mmol  $\text{l}^{-1}$ ) and 1 Hz stimulation frequency, a small increase in basal tension of guinea pig papillary muscles was observed, but without arrhythmic activity.

Figure 2 shows the corresponding action potentials. In guinea pig papillary muscles 500  $\mu\text{mol l}^{-1}$  vanadate broadened the action potential by about 15% at both 30 and 90% repolarisation, whereas in left atria 50  $\mu\text{mol l}^{-1}$  vanadate produced a shortening of the action potential by 60 and 70% at 30 and 90%

**Table 1** Enzyme activities of bovine and guinea pig heart preparations and the inhibitory effect of orthovanadate on the  $\text{Na}^+$ ,  $\text{K}^+$ -ATPase

Beef	Activity	Atria		Ventricle	
		$\text{Mg}^{2+}$ -ATPase	$(\text{Na}^+ + \text{K}^+)\text{ATPase}$	$\text{Mg}^{2+}$ -ATPase	$(\text{Na}^+ + \text{K}^+)\text{ATPase}$
	$\text{ID}_{50}$	$\mu\text{M Na}_3\text{VO}_4$			
			$0.59 \pm 0.14$	$0.60 \pm 0.14$	
Guinea pig	Activity	Atria		Ventricle	
		$\text{Mg}^{2+}$ -ATPase	$(\text{Na}^+ + \text{K}^+)\text{ATPase}$	$\text{Mg}^{2+}$ -ATPase	$(\text{Na}^+ + \text{K}^+)\text{ATPase}$
	$\text{ID}_{50}$	$\mu\text{M Na}_3\text{VO}_4$			
			$0.75^*$	$0.62 \pm 0.13$	

Membrane ATPase preparations were derived using the method of Akera *et al.*<sup>7</sup>. Enzyme activities were determined with a coupled spectrophotometric assay<sup>8</sup>, in the presence of 50–100  $\mu\text{g}$  enzyme protein and (mmol  $\text{l}^{-1}$ )  $\text{Na}^+$  100,  $\text{K}^+$  10,  $\text{Mg}^{2+}$  5 and ATP 3, at 37 °C, pH 7.4, and were measured in  $\mu\text{mol PO}_4$  per mg protein per h. The  $\text{Mg}^{2+}$ -ATPase activity was measured in the presence of 1 mmol  $\text{l}^{-1}$  ouabain. Each activity is the result of four separate preparations determined in triplicate and each  $\text{ID}_{50}$  value the result of four determinations (with exception\*, where  $n = 1$ ) prepared from 48 guinea pigs. Values are means  $\pm$  s.e.m.

repolarisation, respectively. The upstroke velocity of the action potential of both atria and papillary muscles remained nearly unchanged. Similar results were obtained from atrial and ventricular preparations of cat and bovine heart. The time course of the vanadate effect on transmembrane potentials correlated with that of the change in inotropy.

The specific activities of the  $\text{Mg}^{2+}$ - or  $\text{Na}^+ + \text{K}^+$ -activated ATPase for bovine atrial and ventricular tissues are shown in Table 1. Despite the difference in enzyme activities, concentration–response curves for the action of sodium orthovanadate gave similar  $\text{ID}_{50}$  values for the inhibition of bovine atrial and ventricular  $\text{Na}^+ + \text{K}^+$ -activated ATPase. Guinea pig ventricular and atrial ( $\text{Na}^+ + \text{K}^+$ )ATPase was inhibited to a similar extent,

**Fig. 2** Action potentials from guinea pig papillary muscle (left upper trace) and from the left atrium (left lower trace) in control conditions (C) and under  $\text{Na}_3\text{VO}_4$  (14 min 500  $\mu\text{mol l}^{-1}$  for papillary muscle and 8 min 50  $\mu\text{mol l}^{-1}$  for the atrium). The related force of contraction in control and test conditions is shown in the right traces. The upstroke velocities of the action potentials were not significantly influenced by vanadate, being 150  $\text{Vs}^{-1}$  for the papillary muscle and 197  $\text{Vs}^{-1}$  for the atrium.

although the atrial enzyme activity was too low to allow more than one estimation in a preparation using 96 atria.

The positive and negative inotropic actions of vanadate are accompanied by a similar inhibition of the  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$  of ventricular and atrial preparations, despite a higher activity of the  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$  from ventricular myocardium. Negative inotropic changes occur at concentrations ( $1\text{--}100\ \mu\text{mol l}^{-1}$ ) which induce a 55–95% inhibition of bovine cardiac  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$  preparations and a 15–60% inhibition of rubidium uptake in red blood cells<sup>4</sup>, whereas positive inotropic changes ( $50\text{--}500\ \mu\text{mol l}^{-1}$ ) correspond to a 90–100% inhibition of  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$  preparations and a 55–80% inhibition of rubidium uptake<sup>4</sup>. It remains to be explained why high concentrations of vanadate ( $>1\ \text{mmol l}^{-1}$ ), which strongly inhibit  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$  preparations, do not produce arrhythmias similar to those observed with high doses of cardiac glycosides.

Positive and negative inotropic effects correlate well with a broadening and shortening of the action potential, respectively. Therefore, we conclude that differing inotropic effects of vanadate are mainly due to the alteration of the transmembrane potential, but not primarily to the inhibition of cardiac  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ . Another striking property of vanadate is its concentration-dependent stimulatory effect on the adenylate cyclase of rat fat cell membranes<sup>9</sup>. It is still possible that the positive inotropic action of vanadate on ventricular myocardium is caused by an increase in intracellular cyclic AMP. However, the negative inotropic effect of vanadate in atria which occurs at lower concentrations seems to be due to a shortening of the action potential.

## Endogenous digitalis-like activity in the plasma of the toad *Bufo marinus*

CARDIAC GLYCOSIDES derived from plants have a major role in the pharmacotherapy of cardiac disease, and, because they bind to and inhibit  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ , are important in studies of ion transport mechanisms. In the animal kingdom, structurally related compounds with cardiotonic activity have been shown to exist in the poison glands of bufonid toads<sup>1</sup>, but this area has received little attention. Recently we developed a sensitive radioreceptor assay for the detection of endogenous 'digitalis-like' agonists in animals<sup>2</sup>. This assay depends on the ability of a substance to compete with  $^3\text{H}$ -ouabain for binding to  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$  on human red cells. Using this assay, together with assays for inhibition of K transport and  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$  activity, we found high concentrations of 'digitalis-like' activity in the skin of several species of Amphibia<sup>2</sup>. Although this activity is presumably present in skin as a protective toxin, it is possible that it might, under some circumstances,

**Fig. 1** Effect of ouabain (●) or serum (○) on the binding of  $^3\text{H}$ -ouabain to human RBC was assessed by a modification of the method of Gardner and Conlon<sup>4</sup>. Heparinised blood was washed 4 times with 140 mM choline chloride at 4 °C, the buffy coat was removed and RBC were resuspended at a haematocrit of 4% in an assay buffer of 140 mM NaCl, 30 mM HEPES and 10 mM glucose, pH 7.4. To 900  $\mu\text{l}$  of this RBC suspension was added 100  $\mu\text{l}$  of various dilutions of ouabain or serum and these mixtures were incubated at 37 °C for 1 h. Cells were then sedimented at 1,500 r.p.m., followed by resuspension in 225  $\mu\text{l}$  of the fresh assay buffer containing  $5 \times 10^{-10}\ \text{M}$   $^3\text{H}$ -ouabain (8 Ci mmol<sup>-1</sup>, NEN). After incubation at 37 °C for 70 min, bound and free ouabain were separated by washing 4 times in microfuge tubes with 140 mM choline chloride, followed by addition of 10% perchloric acid to the pellet and inversion of the tube into a scintillation vial containing Aquafuor (NEN). Each assay contained duplicate tubes in which  $^3\text{H}$ -ouabain binding was carried out in the presence of  $10^{-4}\ \text{M}$  unlabelled ouabain. This was taken to represent nonspecific binding, and was always less than 10% of total  $^3\text{H}$ -ouabain bound. The per cent of  $^3\text{H}$ -ouabain specifically bound to each group of cells was determined by subtracting the per cent bound to cells in the presence of  $10^{-4}\ \text{M}$  ouabain from the per cent actually bound in each experimental tube. This specific binding for each tube was divided by the specific binding to cells which were never exposed to serum or unlabelled ouabain, and this value was multiplied by 100, to give the value plotted on the vertical axis. The points which are plotted represent the mean of duplicates which varied less than 5%. The ouabain concentration on the abscissa represents the concentration in 1.0 ml of preincubation mix.

also function as an endogenous inhibitor of  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ . We now demonstrate, using both receptor and immunoassays, that high concentrations of digitalis-like activity are present in the plasma of the toad, *Bufo marinus*. As cellular  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$  would presumably be exposed to this endogenous digitalis-like activity, it may have an important, but as yet undetermined, function in this species.

Pre-exposure of human red blood cells (RBC) to dilutions of *Bufo marinus* serum followed by washing and resuspension in fresh buffer, caused a dose-dependent inhibition of subsequent  $^3\text{H}$ -ouabain binding to these cells. The dilution curve produced by serum was parallel to that produced by unlabelled ouabain (Fig. 1), 50% inhibition of  $^3\text{H}$ -ouabain binding being caused by a 1/20,000 dilution of serum and 95% inhibition being caused by a 1/1,000 dilution. Assuming that the activity has a binding affinity for human RBC  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$  that is similar to that of ouabain, the apparent serum concentration in five toads ranges from  $2$  to  $5 \times 10^{-5}\ \text{M}$ . *Rana pipiens*, whose skin has little or no detectable activity (J. S. F. and Daly, in preparation), also had no serum activity detectable, even when tested at 1/10 dilution (data not shown). The digitalis-like activity was unaffected by heating to 100 °C for 15 min, but 95% of the activity was lost after dialysis for 48 h.

To characterise the ouabain binding sites on the  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$  of bufonid RBC, we washed cells six times in 15 volumes of buffer to remove circulating digitalis-like activity, and then performed a  $^3\text{H}$ -ouabain binding assay as with human RBC. No specific  $^3\text{H}$ -ouabain binding was detectable over a range of tracer concentrations from  $5 \times 10^{-10}$  to  $5 \times 10^{-8}\ \text{M}$ , whereas binding was easily detectable in the same number of human RBC (data not shown).

Serum from *Bufo marinus* cross-reacted strongly in a digitalis immunoassay. Serial dilutions produced displacement nearly parallel to that produced by digitalis itself (Fig. 2). In contrast, human serum produced no displacement. The data indicate that 1  $\mu$ l of bufonid serum contains 0.05 ng of immunoreactive digitalis-like activity.

Preincubation of bufonid serum with antibodies to either digitalis or ouabain blocks the receptor competition (Fig. 3). Thus the  $^3$ H-ouabain binding-inhibitory activity seems to be caused by the same molecular species that cross-reacts with antibodies to digitalis and ouabain. This immunological evidence represents entirely independent confirmation that bufonid serum contains high concentrations of a digitalis-like activity.

These data suggest that the concentration of serum digitalis-like immunoactivity is  $\sim 10^{-7}$  M. When compared to the concentration as estimated by competition for receptor binding  $2-5 \times 10^{-5}$  M, it seems that the receptor binding activity of this molecule has been better conserved than has its cross reactivity with anti-digitalis and anti-ouabain antibodies. Direct structural studies will determine its precise relationship to the cardiac glycosides, and to known bufotoxins.

Several questions remain unanswered by these studies. First, although digitalis-like activity is present by both receptor-competition and immunological criteria, it remains to be shown that this serum activity is capable of inhibiting the activity of  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ . Studies suggest that the serum activity is a fully potent inhibitor of the human enzyme (J. S. F. unpublished results). Second, it is not certain by what means *Bufo marinus* can survive with a serum concentration equivalent to more than 1,000 times the concentration of digitalis that produces toxicity

**Fig. 2** Dilution curves for digitalis (●) and bufonid serum (○) in a radioimmunoassay for digitalis. The immunoassay was carried out using a kit supplied by Corning Medical. Reagents include rabbit anti-digoxin antibody which is covalently linked to glass particles and suspended in phosphate-buffered saline with 1% bovine serum albumin, and  $^{125}\text{I}$ -digoxin tracer, comprising  $^{125}\text{I}$ -tyrosine linked to the digoxin molecule. The assay is carried out at room temperature in a total volume of 500  $\mu$ l. The indicated amounts of digitalis are added to the assay tubes in 100  $\mu$ l of pooled human serum to develop the dilution curve for digitalis. The indicated volumes of bufonid or human serum (▲) are similarly added to the assay tubes, with the difference between the indicated volume and 100  $\mu$ l being added as 140 mM NaCl. After incubation for 30 min at room temperature, glass beads were centrifuged at 1,600g for 10 min, supernatants decanted, and radioactivity in the pellets counted in a gamma counter. Points represent the mean of duplicates which varied less than 5%. Very similar results were obtained with serum from two other *Bufo marinus* toads. In this assay, digitoxin shows 3% cross-reactivity, and ouabain, testosterone, progesterone and spironolactone show negligible cross-reactivity.

**Fig. 3** Effect of anti-digitalis and anti-ouabain antisera on the ability of bufonid serum to inhibit  $^3\text{H}$ -ouabain binding to human RBC. *Bufo marinus* serum (BMS) was diluted 1/1,000 in an assay buffer of 140 mM NaCl, 30 mM HEPES and 10 mM glucose, pH 7.4. A 200  $\mu$ l aliquot of this BMS was incubated with 50  $\mu$ l of buffer, or with 50  $\mu$ l of sheep anti-digitalis serum, rabbit anti-ouabain serum or normal human serum which had been diluted in assay buffer to yield the final dilution indicated on the figure. A control tube comprised assay buffer alone. These tubes were incubated at 37  $^{\circ}\text{C}$  for 1 h, followed by the addition of 750  $\mu$ l of human RBC which had been washed 4 times in 140 mM choline chloride and then suspended in assay buffer, to give a final haematocrit of 5%. After an additional incubation for 1 h at 37  $^{\circ}\text{C}$ , cells were sedimented at 1,500 r.p.m., followed by resuspension in 225  $\mu$ l of fresh assay buffer containing  $5 \times 10^{-10}$  M  $^3\text{H}$ -ouabain (8 Ci mmol $^{-1}$ , NEN). After a final incubation at 37  $^{\circ}\text{C}$  (for 70 min, bound and free ouabain were separated by washing 4 times in microfuge tubes with 140 mM choline chloride, followed by addition of 10% perchloric acid to the pellet and inversion of the tube into a scintillation vial containing Aquaflo NEN). Each assay contained duplicate tubes in which  $^3\text{H}$ -ouabain binding was carried out in the presence of  $10^{-4}$  M unlabelled ouabain. This was taken to represent nonspecific binding, and was always less than 5% of total  $^3\text{H}$ -ouabain bound. The data shown are representative of two other experiments not described.

in man. *Bufo marinus* is known to be resistant to the effects of cardiac glycosides, requiring 100 times more ouabain to stop its heart *in vivo*, or to inhibit  $\text{Na}^+$  transport across its bladder *in vitro* than does *Rana pipiens*<sup>4</sup>. This relative resistance to ouabain is consistent with our observation that tracer  $^3\text{H}$ -ouabain binds poorly to bufonid cells. Recent experiments suggest that the bufonid enzyme binds ouabain with low affinity (J. S. F., unpublished results).

Although *Bufo* is clearly relatively resistant to the action of digitalis, high concentrations of this substance, in the range which we estimate (by receptor assay) to be present in its serum, inhibit short circuit current across the bladder of this species *in vitro*<sup>3</sup>. For this reason, it is possible that sufficient activity is bound to the enzyme at prevailing concentrations to tonically inhibit ATPase activity. Preliminary studies demonstrate that bladder from *Bufo marinus* contains easily detectable digitalis-like activity by receptor assay and immunoassay. Studies are in progress to determine what fraction of this extractable activity is actually bound to the bufonid  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$ . This should be of interest because the toad bladder is often used as a model system for  $\text{Na}^+$  transport in the distal nephron of the mammalian kidney. Perhaps it accounts in part for the observation that short circuit current across the toad bladder *in vitro* increases during equilibration of the bladder in buffer.

Thus we have demonstrated for the first time that a digitalis-like substance circulates naturally in the plasma of an animal. The effect of this circulating digitalis-like activity on the physiology of *Bufo marinus* is currently unclear, and the possibility that it tonically inhibits or regulates the  $(\text{Na}^+ + \text{K}^+)\text{ATPase}$  in this species needs further investigation.

We thank Betsy Marsh for technical assistance and Dr Vincent Butler for antibodies to digitalis and ouabain. Toads were obtained from Connecticut Valley Biologic Supplies.

## Circular hydrogen bonds

CIRCULAR hydrogen bonds present a new, experimentally demonstrated principle showing how hydration water molecules and hydroxyl groups of macromolecules can cooperate to form a network-like pattern. Quantum chemical calculations show that chain-like H-bonds in the crystal lattice<sup>1</sup> are energetically favoured above individual ones<sup>2,3</sup>. This is due to the cooperative effect, which leads to increased H-bonding activity of an OH-group if it is already accepting or donating an H-bond. These linear structures can close up to form circular arrangements comprising four and more OH-groups<sup>4-6</sup>. Such circles have actually been described for crystal structures of ice<sup>7</sup> and of ice clathrates<sup>8</sup>, but in these cases the water molecules within the circles are related by crystallographic symmetry elements and are therefore not independent of each other. One should expect to find lattice-independent circular H-bonds in crystal structures of large O—H-rich molecules which co-crystallise with water of hydration, conditions which are satisfied by the cyclodextrin family. The smallest member,  $\alpha$ -cyclodextrin ( $\alpha$ -CD; cyclohexaamylose), consists of six  $\alpha$ (1,4)-linked glucose molecules and contains six primary and 12 secondary hydroxyl groups ((C<sub>6</sub>H<sub>10</sub>O<sub>5</sub>)<sub>6</sub>, molecular weight 973). From aqueous solution,  $\alpha$ -CD crystallises as hexahydrate,  $\alpha$ -CD·6H<sub>2</sub>O, and this complex, with a total of 120 hydroxyl groups (4 × 18 from  $\alpha$ -CD and 4 × 12 from the six H<sub>2</sub>O) in one unit cell has been studied by X-ray and neutron diffraction methods (ref. 9, and Klar, Hingerty and W.S., unpublished). Two other complexes, a second modification of the hexahydrate (K. Lindner and W.S., unpublished) and  $\alpha$ -CD·methanol·4H<sub>2</sub>O (ref. 10) have been investigated by X rays. As refinement in all cases is around  $R = 4\%$  for data extending to 0.89 Å resolution, hydrogen atom positions could be assigned. I discuss here results obtained from the X-ray/neutron study of  $\alpha$ -CD·6H<sub>2</sub>O.

Figure 1 shows a small, relevant section of the crystal structure of  $\alpha$ -CD·6H<sub>2</sub>O obtained from the X-ray/neutron study. Three circular H-bonded structures can be distinguished, one six-membered and two five-membered, all connected by water molecules W(1) and W(4). Two chain-type, linear H-bond structures extend on the left and right hand sides, linked with the circles by W(2) and W(4). Both chain structures with asymmetrical lengths of seven and eight O—H groups are formed by unidirectional O—H...O bonds which indicate the cooperative effect. As similar chains occur in small as well as in large molecule crystal structures<sup>1</sup>, they can be considered as general structural elements.

The three H-bonded circles shown in Fig. 1 all differ from each other. The six-membered circle I is formed by three interconnected water molecules W(1), W(2), W(4) and by three  $\alpha$ -CD hydroxyl groups of which O(2)2 and O(3)3 belong to the same molecule and O(2)3 is from a symmetry-related  $\alpha$ -CD. The six oxygen atoms form a distorted hexagon in an approximate boat shape, with W(1) and O(3)3 in bow/stern positions. In

this circle, H-bond cooperation is again effective because all O—H...O bonds run in the same direction. Therefore, this kind of circle is called *homodromic*.

The adjacent five-membered circles II and III comprise water molecules W(1) and W(4). Circle II contains three hydroxyl groups, of which two, O(2)6 and O(3)1, originate from one  $\alpha$ -CD molecule, and O(6)2 is from a symmetry-related molecule. W(4) acts as a double H-bond donor and thus generates two ...O—H...O—H chains which collide at the double acceptor O(3)1. Because this circle consists of two counter-running chains, it is called *antidromic* (circles with more randomly orientated chains would be called *heterodromic*). In circle III, in addition to water molecules W(1) and W(4), a third water, W(3), is enclosed and the two hydroxyl groups belong to two different  $\alpha$ -CD molecules. This circle is also *antidromic*, as W(3) is a double donor and W(1) a double acceptor for H-bonds. The H...O(6)6 distance, 2.72 Å is unusually long because this hydrogen is also bonded to O(6)1B at 2.85 Å and thus forms a bifurcated H-bond. Based on the sum of the van der Waals potential minimum radii, 1.50 Å for H and 1.65 Å for O, all H...O distances < 3.15 Å can be called bonding interactions and the H...O(6)6, O(6)1B distances are well within this range<sup>11</sup>.

It is remarkable that the three circles share the two water molecules W(1), W(4). The latter are not only used to fill empty gaps between the  $\alpha$ -CD molecules but they are also fully integrated into the H-bonding scheme. We can assume that the circular H-bonds are made possible through the water molecules which, because of their quadruple functionality and their low  $pK$  value ( $pK = 7$ ) relative to the  $\alpha$ -CD hydroxyl groups ( $pK \sim 12.3$  (refs 12,13)), can act as connectors and as shunts. The commonly observed tetrahedral arrangement of the H-bonded ligands is barely satisfied. Only W(2) and W(4) show approximate tetrahedral configuration (with O...W...O angles in the range 94° to 139°); the tetrahedron around W(1) is very distorted (angular range 66° to 142°) and the ligands around W(3) are in a planar-trigonal arrangement.

Quantum chemical studies on the three circles described here have shown that the total energy in each circle is about 2-4 kcal per circle smaller than the sum of the corresponding individual H-bonds (Lesyng and W.S., unpublished). The gain in energy on formation of circular H-bonds is thus similar to that calculated

**Fig. 1** A section of the  $\alpha$ -CD·6H<sub>2</sub>O crystal structure showing circular and chain-like H-bonds. The latter are marked by arrows, the former by roman numerals I-III. Circular arrows indicate the direction of the O—H...O hydrogen bonds. Circle I is homodromic and circles II, III are antidromic. Water and  $\alpha$ -CD hydroxyl oxygens are indicated by W and O, respectively; for further numbering see ref. 10. Ranges for O...O; H...O distances (Å) and O—H...O angles in H-bond circle I are 2.692-3.016 Å; 1.75-1.95 Å; 169-176°; in circle II, 2.747-3.021 Å; 1.86-2.14 Å; 150-171°, in circle III, 2.831-3.339 Å; 1.71-2.72 Å; 117-171°.

for chain-like H-bonds<sup>2,3</sup>, but the latter are more frequently encountered because the former are obviously restricted to large unit cells containing many hydroxyl groups and water molecules. Circular H-bonds might exist at the surfaces of large, hydrophilic molecules where, in combination with isolated and with chain-like H-bonds, they can link existing OH-groups or other hydrophilic residues using water molecules as connectors and shunts. It is likely that a pattern of circular and linear H-bonds can form, providing the basis for more extensive hydration shells. It is also tempting to regard the flickering cluster structure of bulk water<sup>14</sup> and the clathrate shells around hydrophobic molecules<sup>8</sup> as a population of predominantly five- and six-membered circular H-bonds.

## Calcium-dependent regulation of protein synthesis and degradation in muscle

MUSCLE proteins undergo continuous intracellular turnover as do proteins in other cells<sup>1,2</sup>. Furthermore, hormones, nutrients and work load can alter rates of protein synthesis and degradation in muscle, resulting in growth or atrophy of these tissues<sup>1,2</sup>. In hereditary muscular dystrophies, where there is prominent wasting of the affected tissues, rates of both total protein synthesis and degradation are elevated<sup>3–10</sup>. The immediate cause of this muscle atrophy is the imbalance resulting from an increase in protein degradation which exceeds a smaller enhancement in average protein synthesis. No simple explanation based on a defect in the response of dystrophic cells to known hormonal or nutritional factors has satisfactorily explained the elevation in the rates of both protein synthesis and degradation. We have now investigated the possible role of increased cellular  $\text{Ca}^{2+}$  as a mediator of such changes in protein metabolism based on other known structural and biochemical alterations in dystrophic muscles<sup>11,12</sup>. Lesion(s) involving membranes in muscle as well as other cells occur in hereditary dystrophies, including the main human form, Duchenne dystrophy<sup>11,12</sup>. One characteristic of the dystrophic plasma membrane seems to be an increased permeability to the high concentrations of  $\text{Ca}^{2+}$  normally present in extracellular fluid<sup>11,12</sup>. In addition, studies have suggested a decreased ability of sarcoplasmic reticulum to sequester  $\text{Ca}^{2+}$  in dystrophic muscles<sup>13,14</sup>. Thus, it is possible that increased  $\text{Ca}^{2+}$  might be responsible for the stimulation of both protein synthesis and degradation which occurs in these muscles. To test this idea, we have experimentally increased the uptake of external  $\text{Ca}^{2+}$  into rat muscles by using the divalent cation ionophore, A23187.

The ability of this ionophore to increase the transport of  $\text{Ca}^{2+}$  across membranes has resulted in its application as a widely used tool for the study of many  $\text{Ca}^{2+}$ -dependent cellular processes<sup>15</sup>. The experiments reported here demonstrate that increased movement of  $\text{Ca}^{2+}$  into muscle can produce effects which closely resemble dystrophic muscle and that the increased net catabolism can be reversed by certain factors.

We have studied the effect of A23187 in paired, contralateral rat soleus muscles incubated *in vitro* in defined media. Previous studies have shown that such isolated muscle preparations remain viable and maintain linear rates of both protein synthesis and degradation for at least several hours<sup>16,17</sup>. In these conditions, when tension is not maintained, rates of degradation exceed synthesis. For measurements of protein synthesis, incorporation of  $^{14}\text{C}$ -tyrosine into total protein was measured. This amino acid was chosen because it is not metabolised in muscle and does not itself alter the rates of protein synthesis or degradation<sup>16</sup>. To determine absolute rates of synthesis from  $^{14}\text{C}$ -tyrosine incorporated into protein, it was assumed that the intracellular tyrosine-specific activity reflected the tRNA precursor pool. This assumption is valid when high levels of tyrosine (0.5 mM) are added to the medium causing its specific activity to approach that of the intracellular pools<sup>18</sup>. When A23187 ( $10\text{ }\mu\text{g ml}^{-1}$ ) was added to the medium, rates of total protein synthesis were increased by 44% (Table 1). This concentration of A23187 produced maximal stimulation of both protein synthesis and degradation. Addition of A23187 to muscles incubated in calcium-free medium did not affect protein synthesis, indicating a mode of action involving movement of extracellular  $\text{Ca}^{2+}$  into these cells.

Protein degradation was measured in two ways. In one method, net protein degradation was first determined as the amount of total tyrosine released with time into the muscle pools and medium<sup>16</sup>. The absence of metabolism of this amino acid means that the production of free tyrosine must represent the difference between proteolysis and protein synthesis. Addition of A23187 increased tyrosine release by 114% (Table 1). As protein synthesis is elevated in such conditions (Table 1), this increase in released tyrosine actually represents an underestimate of the absolute increase in the amount of protein degradation occurring. To determine rates of protein breakdown, the rates of synthesis and net degradation can be summed. This quantity increased by 71% on addition of the ionophore. An alternative method of measuring degradation involves the addition of cycloheximide to eliminate re-utilisation of amino acids<sup>16</sup>. Although cycloheximide may reduce absolute rates of degradation, the regulatory effects of various physiological factors on proteolysis can still be measured<sup>1,16</sup>. In the presence of cycloheximide, A23187 stimulated tyrosine release by 43% (Table 1).

We then carried out experiments to characterise the increased protein breakdown caused by the  $\text{Ca}^{2+}$  ionophore. As in our experiments on protein synthesis, A23187 had no effect on rates of proteolysis in the absence of extracellular  $\text{Ca}^{2+}$  (Table 1), supporting a mechanism requiring movement of  $\text{Ca}^{2+}$  into the muscle cells. Interestingly, removal of extracellular  $\text{Ca}^{2+}$  by itself reduced degradation. To study the degradation which occurs with elevated intracellular  $\text{Ca}^{2+}$ , we tested the effect of leupeptin on proteolysis (Table 2). This non-toxic, highly specific protease inhibitor has been previously shown to retard muscle degeneration, proteolysis and myofibrillar disassembly without affecting protein synthesis<sup>19–21</sup>. Addition of leupeptin inhibited the elevated rates of degradation which occurred in the presence of A23187 by 32% (– cycloheximide) and 21% (+ cycloheximide). A similar degree of inhibition was also seen in the absence of ionophore, as described previously<sup>20</sup>.

Several studies have reported that protein synthesis and/or degradation in isolated muscles or muscle cells may be influenced by electrical stimulation and even passive stretch<sup>2,22–27</sup>. As such processes also affect the levels of free intracellular  $\text{Ca}^{2+}$ , we investigated the relationship of tension to our ionophore experiments. Muscles were either incubated in a

a, Normal female rats (40–55 g) were killed by cervical dislocation and paired soleus muscles immediately removed with tendons intact and weighed. Each muscle was preincubated in the presence or absence of  $10 \mu\text{g ml}^{-1}$  A23187 (Lilly) for 1 h at  $37^\circ\text{C}$ . The incubation medium (3.0 ml) also contained Krebs–Ringer bicarbonate solution saturated with 95%  $\text{O}_2$ –5%  $\text{CO}_2$  and supplemented with 10 mM glucose, 5× plasma levels of the branched chain amino acids (valine, isoleucine and leucine), and 0.1 unit  $\text{ml}^{-1}$  insulin<sup>16</sup>. A23187 was dissolved in ethanol and the final concentration of ethanol in all incubations was adjusted to 0.5% v/v. This amount of ethanol did not affect protein synthesis or degradation. After 1 h, the muscles were blotted and transferred to fresh medium of the same composition but containing in addition  $^{14}\text{C}$ -tyrosine (0.06  $\mu\text{Ci ml}^{-1}$ ) and unlabelled tyrosine (0.5 mM). The muscles were incubated for 1 h at  $37^\circ\text{C}$  and then placed in 10% trichloroacetic acid and protein synthesis was measured as described previously<sup>16</sup>. Determination of synthesis was carried out by correcting rates of  $^{14}\text{C}$ -tyrosine incorporation into acid-precipitable protein using the specific activity of the intracellular tyrosine pool<sup>16</sup>. For measurement of net protein degradation muscles were incubated without tyrosine to allow accurate measurement of the release of free tyrosine into the muscle pools and medium. Omission of tyrosine has no effect on rates of muscle protein synthesis or degradation<sup>16</sup>. After 1 h of preincubation the tyrosine content of the muscle pools was in a steady state in the presence or absence of ionophore; therefore, net protein degradation measured during the second hour was proportional to tyrosine appearing in the medium during that period. Tyrosine was measured fluorometrically as previously described<sup>16</sup>. Protein degradation was measured similarly except that cycloheximide (0.5 mM) was added to both the preincubation and incubation media. b, Muscles were treated as in a except that the Krebs–Ringer bicarbonate buffer was prepared without calcium but containing the calcium chelator EGTA (2 mM). Results are expressed as the mean value  $\pm$  s.e.m.,  $n = 6$ .  $P$  values were calculated for the paired muscle differences using the Student  $t$ -test. NS, not significant.

\*  $P < 0.005$ .†  $P < 0.003$ .

flaccid state as in Tables 1 and 2 or were incubated with slight passive tension by pinning the tendons so the muscle was maintained at approximately 110% of rest length. When muscles were incubated under tension without ionophore, no effect on synthesis was detected (Table 3). Such results confirm earlier studies with the adult soleus which showed that active or passive tension did not increase synthesis in similar conditions<sup>2,25</sup>. In contrast, fixing the length of the soleus in the presence of A23187 caused a further (23%) increase in protein synthesis above that caused by the ionophore alone (Table 3). Although passive tension alone had no effect on synthesis, as expected, the addition of A23187 to pinned muscles produced a large increase in synthesis (70%) equal to the sum of the above two effects (Table 3).

The increase in synthesis produced with A23187 may result from higher average intracellular  $\text{Ca}^{2+}$  levels than those which occur on intermittent stimulation or stretch as described previously<sup>2,25</sup>. Stimulation may, however, produce higher transient  $\text{Ca}^{2+}$  increases, which would explain the greater peak tension produced with stimulation than A23187 in the soleus<sup>28</sup>. Possibly, more frequent stimulation and/or stretch applied for longer periods further increases free  $\text{Ca}^{2+}$  and may account for several reports of increased protein synthesis caused by stimulation or stretch<sup>22–24,26</sup>. In any case, the ability of A23187 to stimulate protein synthesis is seen when the muscles are flaccid, contracting against no load, indicating that the  $\text{Ca}^{2+}$ -dependent increase in synthesis does not require the development of tension. The further enhancement of synthesis seen when ionophore was added to muscles incubated with slight stretch may result from higher  $\text{Ca}^{2+}$  levels produced by longer sarcomere lengths<sup>29</sup> or possibly length-dependent effects on the sarcolemma. Related studies have shown that most of the  $\text{Ca}^{2+}$ -dependent protein synthesis requires RNA synthesis (G. Silver and J.D.E., in preparation).

In contrast to the potentiating effect of tension on  $\text{Ca}^{2+}$ -dependent synthesis, the effect of tension on degradation was opposite to that produced by A23187. Table 3 shows that maintaining muscle tension decreased rates of proteolysis in the presence of A23187. Furthermore, unlike the effect of tension on synthesis (which was only seen in the presence of ionophore), maintaining the muscle under slight stretch also produced a similar inhibition of degradation in the absence of A23187, as previously reported by Goldberg *et al.*<sup>2,25</sup>. Although the mechanisms by which muscle stretch or activity reduce proteolysis are unclear, the present results argue against a  $\text{Ca}^{2+}$ -mediated effect. Further support for this conclusion comes from the observation that, even over a wide range of ionophore concentration, inhibition of degradation was not detected in the absence of tension (data not shown).

There are several possible mechanisms which can explain the

$\text{Ca}^{2+}$ -dependent stimulation of proteolysis.  $\text{Ca}^{2+}$  may modify the structure of muscle proteins, rendering them more susceptible to proteolysis, or it may stimulate the activity of cellular proteases. Activation of proteolysis could involve an increase in the number of muscle lysosomes, leakage of lysosomal enzymes, or increased uptake of proteins into this organelle. Alternatively, mammalian cells are known to contain soluble neutral proteases<sup>30–33</sup>, and  $\text{Ca}^{2+}$ -dependent protease(s) from muscle seem to be capable of initiating myofibrillar degradation and hydrolysing other proteins<sup>31–33</sup>. Direct activation of such non-lysosomal proteases seems an attractive explanation of the ionophore effect on degradation rates, although other indirect mechanisms cannot be excluded.

The actual mechanisms involved in the  $\text{Ca}^{2+}$ -dependent effects described here are unclear, but several factors indicate that they do not involve gross toxic effects on cells. First, elevation of protein synthesis in the presence of the ionophore indicates good viability, as this process is sensitive to small drops in ATP levels. Also, exposure of the muscles to A23187 for 2 h produced no loss of subcellular structure or ability to produce maximum twitch tension on electrical stimulation (T. K., D. Erlij and J.D.E., in preparation). Finally, in previous studies with this muscle no alteration in resting potential was seen with the same concentrations of A23187 ( $10 \mu\text{g ml}^{-1}$ ) producing maximal effects in the present studies<sup>28</sup>. These results differ considerably from the results of certain workers using this ionophore in other systems. For example, studies with frog skeletal muscle have reported contraction accompanied by a decrease in resting potential and dramatic destruction of subcellular structure on exposure to A23187<sup>34</sup>. Such effects may be related to our observations of decreased protein synthesis seen in certain muscle preparations or upon longer exposure to ionophore (data not shown).

**Table 2** Effect of leupeptin on protein degradation in the absence (a) and presence (b) of A23187

Treatment	Net protein degradation (nmol Tyr released per mg per h)		Protein degradation (+cycloheximide) (nmol Tyr released per mg per h)

Muscles were maintained under tension throughout the preincubation and incubation periods by fixing the length of the tissues in a stretched position (110% of rest length) with pinning through the tendons into small plastic supports. Other muscles were incubated in a flaccid state. Ionophore ( $10 \mu\text{g ml}^{-1}$ ) was added as indicated and measurements were carried out as described in Table 1. Differences between mean values for identical conditions tested during different experiments (*a*, *b*, *c*) illustrates day to day variations and the advantage of paired muscle analysis.

\*  $P < 0.025$ .

†  $P < 0.01$ .

‡  $P < 0.003$ .

In related studies we have found that combinations of different degrees of stretch and  $\text{Ca}^{2+}$  can produce effects consistent with muscle hypertrophy as well as atrophy (J.D.E., T.K. and K. Matsumoto, in preparation). However, the observations reported here closely resemble the hereditary muscular dystrophies. Thus,  $\text{Ca}^{2+}$  may be directly responsible for at least a substantial part of the increased protein turnover and net negative nitrogen balance characteristic of muscular dystrophies. Tension seems to be particularly effective in decreasing  $\text{Ca}^{2+}$ -induced net catabolism by increasing synthesis as well as decreasing degradation, and leupeptin seems able to decrease proteolysis in the ionophore-treated muscles. Thus, maintenance of passive tension, and other agents like leupeptin and possibly calcium chelators may be of therapeutic value in the treatment of certain muscular dystrophies.

We thank K. Kameyama and K. Matsumoto for assistance, L. Abbott and R. Ginsberg for preparation of the manuscript, and D. A. Fischman for reading the manuscript. These studies were supported by the Commonwealth Foundation and by grants to J.D.E. from NIH (HL2197002) and the Muscular Dystrophy Association. Leupeptin was from the US-Japan Cooperative Cancer Research Program, and A23187 from R. Hamill (Lilly).

## Cloning and endonuclease mapping of the hepatitis B viral genome

THE virus that causes hepatitis B, or serum hepatitis, seems to infect only humans in nature, and experimental infection has been achieved in only a few additional mammals. The limited host range of the hepatitis B virus (HBV), and its failure so far to infect tissue culture cells have drastically restricted study of this virus and have hindered development of a vaccine for the serious disease that it causes. We report here the cloning of double-stranded HBV DNA in *Escherichia coli* K12, using the unique *EcoRI* cleavage site on the viral genome to introduce the entire HBV DNA molecule into an *EcoRI* cleavage site within the chloramphenicol (Cm) resistance gene of the pACYC184 plasmid vector<sup>1</sup>.

The Dane particle<sup>2</sup>, a particulate form of viral antigen found in the blood of infected patients, seems to be the infectious form of HBV. DNA isolated from Dane particles has a molecular weight of  $2.1 \times 10^6$  (corresponding to an approximate genome length of 3,200 base pairs), and is single-stranded for about 15–45% of its length<sup>3,4</sup>. Using either the endogenous DNA polymerase of the Dane particle<sup>4</sup> or avian myeloblastosis virus RNA-dependent DNA polymerase (reverse transcriptase)<sup>5</sup>, the hepatitis B viral genome can be converted to a double-stranded circular form, which is cleaved by the *EcoRI* endonuclease into a unit length linear structure (A. Siddiqui, F. R. Sattler and W. S. Robinson, in preparation). We have introduced this *EcoRI*-cleaved viral DNA into the *EcoRI* site of the Cm-resistance gene of plasmid pACYC184. The previously reported<sup>4</sup> heterogeneity of Dane particle DNA has been investigated by analysis of multiple separately-cloned DNA molecules, and a restriction endonuclease cleavage map of the HBV genome has been constructed.

The surface antigen of the hepatitis B virus (HBsAg) is known to be antigenically complex; four major subtypes (adw, ayw, adr, ayr) have been identified, and recent immunological evidence suggests that antigenic heterogeneity exists also within each of these subtypes<sup>6</sup>. Siddiqui *et al.* (in preparation) have observed that Dane particle DNA isolated from carriers infected with different hepatitis B viral subtypes show divergent *HincII* and *HaeIII* endonuclease cleavage patterns, and some degree of heterogeneity has been found even within the same subtype. In order to circumvent heterogeneity between different HBsAg subtypes or between different carriers of the same subtype, the DNA used in our initial cloning experiments was isolated from Dane particles of a single HBsAg carrier (subtype adw). This method also allowed us to investigate further the question of possible heterogeneity of hepatitis B viral DNA isolated from a single carrier.

In order to decrease the frequency of recircularisation of the pACYC184 vector plasmid and to maximise formation of composite plasmids, *EcoRI*-cleaved pACYC184 DNA was treated with alkaline phosphatase<sup>7</sup> before addition of *EcoRI*-

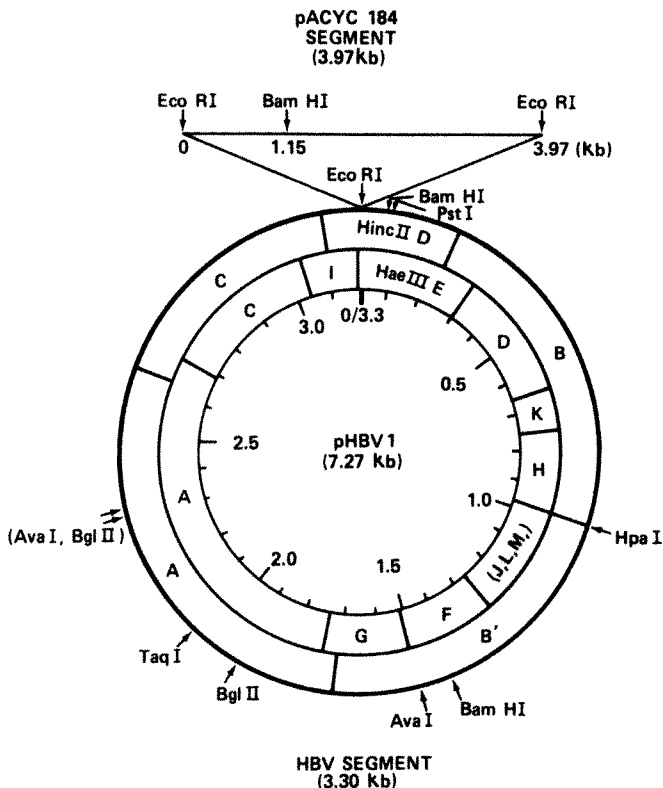

treated Dane particle DNA that had been made double-stranded using the endogenous DNA polymerase. The DNA species were ligated and introduced by transformation into a non-restricting ( $r_{km}^+$ ) mutant *E. coli* C600 (ref. 8); bacteria were plated on nutrient agar plates containing tetracycline (Tc,  $10 \mu\text{g ml}^{-1}$ ) 40 min after the DNA uptake step of the transformation procedure to ensure that individual transformants

**Fig. 1** Cloning and restriction endonuclease analysis of recombinants between Dane particle DNA and the pACYC184 plasmid vector. Dane particle DNA was isolated from the plasma of a chronic hepatitis B surface antigen (subtype adw) carrier 1083 and made fully double-stranded using the endogenous polymerase<sup>4</sup>. 100 ng of this DNA was digested with 0.5 units of *Eco*RI endonuclease (New England Biolabs) for 30 min as previously described<sup>8</sup>. pACYC184 DNA 2  $\mu\text{g}$  isolated as described elsewhere<sup>12</sup> was simultaneously digested with a twofold excess of endonuclease *Eco*RI and treated with 0.2 U of calf intestine alkaline phosphatase (Boehringer) to prevent recircularisation during the subsequent ligation<sup>7</sup>. The reaction was stopped by heating at  $65^\circ\text{C}$  for 10 min, followed by phenol extraction. After precipitation by ethanol, the phosphatase-treated plasmid DNA was mixed with the *Eco*RI-cleaved fully double-stranded Dane particle DNA in a final volume of 50  $\mu\text{l}$ , and ligated using 0.14 U of bacteriophage T4 DNA ligase (New England Biolabs) for 8 h at  $12.5^\circ\text{C}$  in standard conditions<sup>8</sup>. The reaction mixture was added directly to the  $\text{CaCl}_2$ -treated *E. coli* C600 ( $r_{km}^+$ ) for transformation<sup>8</sup>. P3+EK1 containment conditions were used, as specified in the 22 December 1978 recombinant DNA guidelines of the US National Institutes of Health. Transformants were selected on Penassay base agar (antibiotic medium 2, Difco) containing Tc ( $10 \mu\text{g ml}^{-1}$ ). After 24 h at  $37^\circ\text{C}$ , colonies were screened for insertions in the gene that codes for chloramphenicol resistance<sup>1</sup> by streaking clones on plates containing Cm ( $25 \mu\text{g ml}^{-1}$ ). Plasmid DNA was isolated from those clones which were sensitive to Cm as described<sup>12</sup>. Endonuclease digests of one representative plasmid designated pHBV1 were analysed by gel electrophoresis. Vertical agarose (0.7%, Seakem, M.C.I.) gels (20 cm long) were run at 35 mA (ref. 9). pACYC184 and pHBV1 DNAs were treated with the indicated endonucleases and molecular lengths were calculated using *Eco*RI-generated fragments of pRR12 as a size standard (see below) and are accurate within  $\pm 10\%$  (ref. 13). Lanes: (1) pACYC184 DNA, showing uncleaved superhelical dimers and higher multimers; (2) pHBV1 recombinant DNA, showing uncleaved superhelical monomers and higher multimers; (3) *Hind*III-cleaved pACYC184 DNA, showing a single linear fragment (3.97 kilobases); (4) *Hind*III-cleaved pHBV1 recombinant DNA, showing linear fragment (7.91 kilobases), as HBV DNA is not cleaved by this enzyme; (5) *Eco*RI-cleaved pACYC184 DNA, showing single linear fragment (3.97 kilobases); (6) *Eco*RI-cleaved pHBV1 showing two fragments (3.97 and 3.3 kilobases); (7) *Eco*RI-generated fragments of plasmid pRR12 used as molecular length standards<sup>13</sup>. The lengths of the fragments shown are (from top to bottom) 20.39, 12.08, 11.40, 10.88, 7.55, 6.04, 5.29, 4.83, 4.09, 2.70, 1.66, 1.53 and 1.13 kilobases.

**Fig. 2** Autoradiogram of pHBV1 DNA after endonuclease digestion and hybridisation with a nick-translated Dane particle DNA probe. The fractionation of endonuclease cleaved DNA was as described in Fig. 1, except that a 1.5% agarose gel was used. The DNA was transferred from the agarose slab gels onto nitrocellulose filters (Millipore) by the method of Southern<sup>14</sup>. After the transfer, the filter was incubated for 16 h in a  $6\times\text{SSC}$  solution containing prehybridisation buffer (0.02% each of Ficoll, polyvinylpyrrolidone and bovine serum albumin)<sup>15</sup>. Dane particle DNA was labelled by nick translation<sup>16,17</sup>. The specific activity of the DNA probe was  $5.09\times 10^7$  c.p.m.  $\mu\text{g}^{-1}$ . Initially, the  $^{32}\text{P}$ -labelled DNA ( $1.5\times 10^6$  c.p.m.) was denatured in a boiling water bath for 20 min in the presence of  $1.3 \text{ mg ml}^{-1}$  sonicated salmon sperm DNA (total volume 1.2 ml), chilled briefly, then brought to a final volume of 5 ml hybridisation buffer containing 50% formamide,  $5\times\text{SSC}$ , and 0.2% sodium lauryl sulphate. After removing the prehybridisation buffer, the filter ( $8\times 15 \text{ cm}$ ) was annealed with the HBV probe for 12 h at  $42^\circ\text{C}$  in a sealed plastic bag. It was then washed twice for 1 h each time at  $42^\circ\text{C}$  with 25 ml of the hybridisation buffer and repeated an additional two times with 100 ml  $2\times\text{SSC}$ , air dried and exposed to an X-ray film in the presence of a Dupont Cronex intensifying screen at  $-70^\circ\text{C}$  for 2 h. Lanes: (1) *Eco*RI-cleaved  $^{32}\text{P}$ -labelled Dane particle DNA made double-stranded with endogenous polymerase, to serve as a marker for the location of unit length HBV DNA; (2) *Eco*RI-cleaved pHBV1 DNA; (3)  $^{32}\text{P}$ -labelled nick-translated HBV DNA that has been cleaved with both *Eco*RI and *Hinc*II, to serve as a marker for the sizes of the endonuclease generated fragments from the genome; (4) pHBV1 DNA cleaved with both *Eco*RI and *Hinc*II. Lanes 1 and 3 were exposed to X-ray film before hybridisation was performed. The 94-base pair fragment resulting from the *Eco*RI cleavage of the *Hinc*II 'D' fragment (see Fig. 3) does not appear in the autoradiogram because it is not retained by this gel. The 220-base pair fragment resulting from this same cleavage of *Hinc*II fragment D does not appear in lane 4 because it is incompletely retained on the filters during hybridisation in the conditions used.

**Fig. 3** Map of HBV DNA component of the pHBV1 plasmid, showing cleavage sites for certain restriction endonucleases. The cloned HBV DNA was mapped by a previously described procedure which involves  $^{32}\text{P}$ -end labelling and partial enzyme digestions<sup>10</sup> (data not shown). The HBV DNA insert contains no cleavage sites for the *Hind*III, *Sal*I, *Sma*I, or *Xho*I endonucleases. The *Eco*RI cleavage site was arbitrarily chosen as the zero position for the map.
